#### SPECIMEN DETAILS

ORDERED BY

SPECIMEN TYPE: COLLECTION DATE: **RECEIVED DATE:** REPORT DATE: 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

# **Complete Panel**

# Risk Management

## Type III Hyperlipoproteinemia

## Not Associated with Type III Hyperlipoproteinemia

The patient is negative for both the APOE c.388 T>C (Cys130Arg) and c.526 C>T (Arg176Cys) mutations. The patient's genotype is wild-type, which is the most common genotype in the general population (frequency: >60%).

A patient with wild-type genotype does not have a defect in the apolipoprotein E (APOE), which is an integral structure of lipoprotein particles that have critical roles in blood lipid metabolism and transport. The APOE ε3/ε3 genotype is not associated with increased risk of cardiovascular disease. No action is needed when a patient is normolipidemic.

## Hyperhomocysteinemia - Depression

## No Increased Risk of Hyperhomocysteinemia

The patient does not carry the MTHFR c.665C>T variant. MTHFR enzyme activity is normal.

Patients diagnosed with depression often have low folate levels and homocysteine is a highly sensitive marker of folate status. Functional folate deficiency is indicated by elevated homocysteine. With a normal MTHFR activity, this patient can process folate normally and is unlikely to have elevated plasma levels of homocysteine.

Patients diagnosed with depression: as lower folate levels are associated with poorer antidepressant response, and baseline levels of folate within the normal range predict antidepressant response, testing for homocysteine levels and serum folate levels may be informative for this patient before prescribing methylfolate as an antidepressant-augmenting agent.

## Thrombophilia

## Normal Risk of Thrombosis

The patient does not carry the F5 c.1601G>A variant (also known as Factor V Leiden) or the F2 c.\*97G>A variant (also known as Factor II 20210G>A). The patient's risk of thrombosis is not increased (average risk of clotting is about 1 in 1000 for anyone in a year). However, because this test cannot find all of the inherited reasons for abnormal clotting, other factors may affect this risk assessment.

Assess thrombotic risk based on other genetic and/or circumstantial risk factors such as smoking, obesity, malignancy, prolonged immobilization or surgery.

Estrogen-containing contraceptive and hormone replacement therapy: unless other genetic and/or circumstantial risk factors are present, consider standard prescribing and monitoring practices.

## Hyperhomocysteinemia - Thrombosis

## No Increased Risk of Hyperhomocysteinemia

The patient does not carry the MTHFR c.665C>T variant or MTHFR c.1286A>C variant. MTHFR enzyme activity is normal.

Based on results for the MTHFR c.665C>T and c.1286A>C variants, the patient has normal MTHFR activity and is unlikely to have elevated plasma levels of homocysteine. Hyperhomocysteinemia is associated with a risk for venous thromboembolism (VTE). Unless other risk factors are present, the patient is not expected to have an increased risk for VTE.

MTHFR enzyme activity is normal.

A medication has potentially reduced efficacy, increased toxicity or the patient has an increased risk for the indicated condition. Guidelines exist for adjusting dosage, increased vigilance or the patient has a moderate risk for the indicated condition.	ACTIONABLE	Recommendations based upon publications by international pharmacogenetic expert groups, consortia or regulatory bodies (CPIC, DPWG, FDA. EMA). Recommendations are suitable for implementation in a clinical setting. Guidelines may change as knowledge arises.
The medication can be prescribed according to standard regimens or the patient's risk for the indicated condition is not increased.	INFORMATIVE	There are insufficient or contradictory findings documenting the impact of a given genetic polymorphism or drug interaction. Recommendations are informative and implementation in a clinical setting is optional.

SPECIMEN DETAILS

SPECIMEN TYPE:

COLLECTION DATE:

ORDERED BY

DOB: **RECEIVED DATE:** SEX: REPORT DATE: 11/11/2022 FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE INFORMATIVE Hydrocodone Altered Response to Hydrocodone (OPRM1: Altered OPRM1 Function) The patient carries one copy of the OPRM1 118A>G variant. Acute postoperative and cancer pain: the patient's genotype Vicodin® has been shown to be associated with reduced analgesia and increased opioid side effects at standard or high hydrocodone doses. If the patient fails to respond to increased hydrocodone doses, an alternative opioid may be considered. 🔔 Lansoprazole ACTIONABLE Slightly Decreased to Normal Exposure to Lansoprazole (CYP2C19: Rapid Metabolizer) The patient's genotype may be associated with a slightly decreased lansoprazole exposure following standard dosing. Be Prevacid<sup>®</sup> alert for insufficient response, consider prescribing lansoprazole at standard label-recommended dosage and administration. May consider increasing the recommended dose for certain indications by 50-100% to optimize therapeutic efficacy. INFORMATIVE 🔔 Methylphenidate Decreased Response to Methylphenidate (COMT: Intermediate COMT Activity) Ritalin<sup>®</sup>, Aptensio XR<sup>®</sup>, The patient's genotype result predicts a less optimal response to methylphenidate. Dosage should be individualized according to the needs and response of the patient. Therapy should be initiated in small doses, with gradual weekly Concerta®, Metadate increments. ER<sup>®</sup>, Quillivant ER<sup>®</sup> INFORMATIVE 🔥 Morphine Altered Response to Morphine (OPRM1: Altered OPRM1 Function) The patient carries one copy of the OPRM1 118A>G variant. Acute postoperative and cancer pain: the patient's genotype MS Contin® has been shown to be associated with possible reduced analgesia at standard morphine doses and decreased risk for nausea and vomiting during the first 24-hour postoperative period. Therefore, the patient may require higher doses of this drug. The dosing regimen needs to be individualized for each patient, taking into account the patient's prior analgesic treatment experience. INFORMATIVE 🔔 Olanzapine Non-Response to Olanzapine (CYP1A2: Normal Metabolizer - Higher Inducibility) There is little evidence regarding the impact of CYP1A2 genetic variants on olanzapine response. Smokers may be at risk Zyprexa<sup>®</sup> for non-response at standard doses. Careful monitoring is recommended during dosing adjustment. Smoking cessation may increase plasma drug levels, leading to adverse events. Therefore, therapeutic drug monitoring accompanied by dose reduction may be needed in patients who have guit smoking. ACTIONABLE 🕛 Omeprazole Slightly Decreased to Normal Exposure to Omeprazole (CYP2C19: Rapid Metabolizer) The patient's genotype may be associated with a slightly decreased omeprazole exposure following standard dosing. Be Prilosec<sup>®</sup> alert for insufficient response, consider prescribing omeprazole at standard label-recommended dosage and administration. May consider increasing the recommended dose for certain indications by 50-100% to optimize therapeutic efficacy. **Pantoprazole** Slightly Decreased to Normal Exposure to Pantoprazole (CYP2C19: Rapid Metabolizer) ACTIONABLE The patient's genotype may be associated with a slightly decreased pantoprazole exposure following standard dosing. Be **Protonix**® alert for insufficient response, consider prescribing pantoprazole at standard label-recommended dosage and administration. May consider increasing the recommended dose for certain indications by 50-100% to optimize therapeutic efficacy. Sertraline INFORMATIVE Possible Reduced Response to Sertraline (CYP2C19: Rapid Metabolizer) Zoloft<sup>®</sup> Sertraline can be prescribed at standard label-recommended dosage and administration. If patient does not respond to recommended maintenance dosing, consider an alternative medication. 🕂 Tetrabenazine Normal Sensitivity to Tetrabenazine (CYP2D6: Normal Metabolizer) ACTIONABLE Xenazine<sup>®</sup>

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

For treating chorea associated with Huntington's disease: Individualization of dose with careful weekly titration is required. The first week's starting dose is 12.5 mg daily; second week, 25 mg (12.5 mg twice daily); then slowly titrate at weekly intervals by 12.5 mg to a tolerated dose. The maximum daily dose in CYP2D6 normal metabolizers is 100 mg, with a maximum single dose of 37.5 mg. If serious adverse events occur, titration should be stopped and the dose of tetrabenazine should be reduced. If the adverse event(s) do not resolve, consider withdrawal of tetrabenazine.

# Image: Construction of the second second

Warfarin Dosing Adjustments are Expected (CYP2C9 \*1/\*1; VKORC1 -1639G>A A/A) ACTIONABLE

monitoring accompanied by dose reduction may be needed in patients who have guit smoking.

When initiating warfarin treatment for indications with a target INR of 2-3, consider one of the following methods to estimate dosing requirements:

FDA Label: CYP2C9 and VKORC1 genotype results indicate an expected therapeutic dose of 3-4 mg/day.

Pharmacogenomics algorithms/calculators available at www.warfarindosing.org:

**Caucasians and Asians:** Use the patient's demographics and other clinical factors along with CYP2C9 and VKORC1 genotypes to calculate the expected therapeutic dose.

**Africans and African Americans:** Use the patient's demographics and other clinical factors along with CYP2C9 and VKORC1 genotypes to calculate the expected therapeutic dose.

The provided recommendations in Africans and African Americans apply only when all the following CYP2C9 alleles are tested: \*5, \*6, \*8, \*11.

## Alfentanil Normal Response to Alfentanil

**Pharmacogenetic guidance**: alfentanil is primarily metabolized by CYP3A4 and CYP3A5. Studies in healthy subjects showed that CYP3A5 genotype had no effect on the systemic or apparent oral clearances, or pharmacodynamics of alfentanil. **Polypharmacy guidance**: Alfentanil should be used with caution when prescribed to patients taking CYP3A4 inhibitors or inducers.

**Alfuzosin** UroXatral®

Alfenta®

Coumadin<sup>®</sup>

Normal Response to Alfuzosin

**Pharmacogenetic guidance:** No genetically-guided drug selection or dosing recommendations are available. **Polypharmacy guidance:** Alfuzosin is extensively metabolized by CYP3A4 into pharmacologically inactive metabolites. Alfuzosin is **contraindicated with strong CYP3A4 inhibitors, as the risk for QTc prolongation induced by this drug is increased at higher concentrations**. Take caution when this drug is prescribed with CYP3A4 moderate inhibitors, as drug levels may increase.

Alprazolam

## Normal Response to Alprazolam

Normal Exposure to Amiodarone

**Pharmacogenetic guidance:** Alprazolam is primarily eliminated by metabolism via CYP3A4 and CYP3A5. Genetic polymorphisms of these genes are not expected to affect the efficacy or safety profiles of this drug. **Polypharmacy guidance:** The concomitant use of alprazolam with CYP3A4 inhibitors may result in increased alprazolam levels and prolonged sedation. Impairment of motor skills are also observed with some combinations. Monitor patients for exaggerated sedative effects. If possible, alprazolam should be avoided in patients receiving strong inhibitors of CYP3A4 such as ketoconazole, itraconazole and ritonavir. Drugs that induce CYP3A enzymes may decrease alprazolam levels, which results in a loss of efficacy.

NAME: Patient io284w9 ACC #: io284w9 DOB: 1/1/1900 SEX: SPECIMEN DETAILS

ORDERED BY

**Pharmacogenetic guidance:** Apremilast is primarily eliminated via both hydrolysis and cytochrome P450-mediated oxidative metabolism (with subsequent glucuronidation). Cytochrome P450-metabolism is mediated by CYP3A4, with minor contributions from CYP1A2 and CYP2A6. Genetic polymorphisms of these enzymes are not expected to affect the efficacy or safety profiles of apremilast. **Polypharmacy guidance:** The use of metabolizing enzyme inducers (e.g. rifampin, phenobarbital, carbamazepine, phenytoin) with apremilast is not recommended.

## Normal Response to Aprepitant

Aprepitant Emend-oral®

## ACTIONABLE

**Pharmacogenetic guidance:** Aprepitant undergoes extensive metabolism via N- and O-dealkylations. These pathways are primarily catalyzed by CYP3A4 with minor involvement from CYP1A2 and CYP2C19. The drug is also glucuronidated by UGT1A4 and UGT1A3. No genetically guided drug selection or dosing recommendations are available. **Polypharmacy Guidance:** In presence of moderate and strong CYP3A4 inhibitors, a significantly increased exposure of aprepitant is expected which may lead to adverse reactions. These drugs should be avoided with aprepitant. Strong CYP3A4 inducers can significantly decrease aprepitant exposure resulting in a loss of efficacy. These drugs should also be avoided with aprepitant. Aprepitant is a moderate (dose-dependent) inhibitor, and an inducer of CYP3A4 and an inducer of CYP2C9. Some substrates of these enzymes are contraindicated with aprepitant while others should be closely monitored and their doing adjusted when coadministered with this antiemetic medication.

Abilify®, Aristada®

#### Normal Exposure to Aripiprazole (CYP2D6: Normal Metabolizer)

ACTIONABLE

The patient's genotype is associated with normal aripiprazole exposure. Consider prescribing aripiprazole at standard label-recommended dosage and administration. Careful titration is recommended until a favorable response is achieved.

<u>Daily dosing</u> (oral): the daily maintenance and maximum recommended doses are 10-15 mg and 30 mg, respectively. Reduce dose by 50% if a strong CYP2D6 inhibitor or a strong CYP3A4 inhibitor is co-administered. Reduce the dose to 25% of the usual dose if both a strong CYP2D6 inhibitor and a strong CYP3A4 inhibitor are co-administered. Double the dose if a strong CYP3A4 inducer is co-administered.

Single dosing (intramuscular): consider one single injection of 675 mg of *Aristada Initio* when initiating treatment with *Aristada*. Avoid using *Aristada Initio* if a strong CYP2D6 inhibitor or a strong CYP3A4 inhibitor or a strong CYP3A4 inducer is co-administered.

Monthly dosing (intramuscular): the starting and maintenance monthly recommended dose is 400 mg for *Abilify Maintena* or 441 mg, 662 mg and 882 mg for *Aristada*. For *Abilify Maintena*, reduce the monthly dose to 300 mg if a strong CYP2D6 inhibitor or a strong CYP3A4 inhibitor is co-administered to patients receiving aripiprazole at 400 mg, and reduce dose to 200 mg in patients receiving aripiprazole at 300 mg. For *Aristada*. reduce the dose to the next lower strength if a strong CYP2D6 inhibitor or a strong CYP3A4 inhibitor is co-administered for more than 14 days. For *Abilify Maintena*, reduce the dose to 200 mg if both a strong CYP2D6 inhibitor and a strong CYP3A4 inhibitor are coadministered to patients receiving aripiprazole at 400 mg, and reduce the dose to 160 mg in patients receiving aripiprazole at 300 mg. For *Aristada*. avoid use for patients at 662 mg or 882 mg dose if both a strong CYP2D6 inhibitor and a strong CYP3A4 inhibitor are co-administered. No dosage adjustment is necessary in patients taking 441 mg *Aristada*. if tolerated. If a strong CYP3A4 inducer is co-administered for more than 14 days, avoid using *Abilify Maintena*. For *Aristada*. if a strong CYP3A4 inducer is co-administered for more than 14 days, increase the 441 mg dose to 662 mg; no dose adjustment is necessary for 662 mg and 882 mg doses.

Every 6 weeks or two months dosing with *Aristada* (intramuscular): depending on individual patient's needs, treatment may be initiated with the 882 mg dose every 6 weeks or 1064 mg dose every two months. Reduce the dose to a lower strength: 441 mg every 4 weeks if a strong CYP2D6 inhibitor or a strong CYP3A4 inhibitor is co-administered for more than 14 days. Reduce the dose to a lower strength: 441 mg every 4 weeks if a strong CYP3A4 inhibitor are both co-administered for more than 14 days. If a strong CYP3A4 inhibitor are both co-administered for more than 14 days. If a strong CYP3A4 inducer is co-administered for more than 14 days, no dose adjustment is necessary for the 662 mg, 882 mg or 1064 mg doses, whereas 441 mg dose should be increased to 662 mg.

as asenapine plasma concentrations will increase resulting in more side effects. Cigarette smoking, which induces CYP1A2 activity, has a limited effect on asenapine plasma concentrations. Asenapine is a weak inhibitor of CYP2D6 and its coadministration with paroxetine (both a substrate and an inhibitor of CYP2D6) should be approached with caution. Long -term therapy with strong enzyme inducers (e.g. carbamazepine, phenytoin, rifampin) may decrease asenapine exposure and dosage adjustment may be needed.

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

**Pharmacogenetic guidance:** The predominant metabolic pathway of betrixaban is amide hydrolysis with minor cytochrome P450 enzymes-based metabolism (less than 1% of the drug is metabolized by CYP1A1, CYP1A2, CYP2B6, CYP2C9, CYP2C19, CYP2D6 and CYP3A4). The main elimination pathway of the drugs is biliary excretion followed by urinary excretion. Betrixaban is a substrate for the efflux transport protein P-gp (ABCB1) and while this transporter is polymorphic, genetic variations are unlikely to have a clinically significant impact on betrixaban exposure, and no genotype-based dosing adjustments are available. **Polypharmacy guidance:** Concomitant use with P-gp inhibitors such as amiodarone, azithromycin, verapamil, ketoconazole, clarithromycin results in increased plasma levels of betrixaban and increased risk of bleeding. Dosing reduction and close monitoring are recommended in presence of P-gp inhibitors.

		increased risk of bleeding. Dosing reduction and close monitoring are recommended in presence of P-

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

Celecoxib therapy can be initiated at standard label-recommended dosage and administration.

Consider initiating treatment at the lowest end of the dosing range in geriatric patients. A dosage adjustment may be warranted when celecoxib is administered with CYP2C9 inhibitors or inducers.

**Osteoarthritis, Rheumatoid Arthritis, Ankylosing Spondylitis, Acute Pain, Primary Dysmenorrhea**: Consider using the lowest effective dosage for the shortest duration consistent with the patient treatment goals.

Acute Migraine: Consider using for the fewest number of days per month, as needed.

**Osteoarthritis and Hypertension (co-formulation with amlodipine)**: Consider using the lowest effective dosage for the shortest duration consistent with the patient treatment goals.

Chlorpromazine Normal Sensitivity to Chlorpromazine (CYP2D6: Normal Metabolizer) INFORMATIVE Thorazine 
Normal Sensitivity to Chlorpromazine (CYP2D6: Normal Metabolizer) INFORMATIVE Chlorpromazine is metabolized by CYP2D6, CYP3A4 and flavin-containing monooxygenases. This drug can be prescribed at standard label recommended-dosage and administration. Careful titration is recommended until a favorable response is achieved.

Chlorpropamide Diabinese®

Clobazam

**Onfi**®

Normal Exposure to Chlorpropamide

**Pharmacogenetic guidance**: Chlorpropamide is metabolized mainly by CYP2C9 and to a lesser extent by CYP2C19. While this clearance pathway is diminished in subjects with reduced CYP2C9 activity, such a change has not been shown to be clinically significant. No genetically guided drug selection or dosing recommendations are available. **Polypharmacy guidance**: Co-administration of chlorpropamide with a strong CYP2C9 and/or CYP2C19 inhibitors may result in higher chlorpropamide concentrations possibly leading to hypoglycemia. Co-administration with a strong CYP2C9 and/or CYP2C19 inducers may result in lower chlorpropamide concentrations and a lack of efficacy.

Normal Sensitivity to Clobazam (CYP2C19: Rapid Metabolizer)

ACTIONABLE

INFORMATIVE

The genotype result predicts a rapid metabolizer phenotype, which translates to an increased CYP2C19 function. Rapid metabolizers have a higher capacity to metabolize N-desmethylclobazam, the active metabolite of clobazam. However, there is insufficient data to allow calculation of dose adjustment when clobazam is prescribed. Therefore, the dosing recommendation for normal metabolizers is proposed. Clobazam can be prescribed at standard label-recommended dosage and administration. Individualize dosing within each body weight group, based on clinical efficacy and tolerability. Do not proceed with dose escalation more rapidly than weekly, because serum concentrations of clobazam and its active metabolite require 5 and 9 days, respectively, to reach steady state. Recommended daily dosing:  $\leq$  30 kg body weight: starting dose 5 mg; day 7: 10 mg and day 14: 20 mg; > 30 kg body weight: starting dose 10 mg, day 7: 20 mg and day 14: 40 mg.

**Clonazepam** *Klonopin*® Normal Response to Clonazepam

INFORMATIVE

INFORMATIVE

**Pharmacogenetic guidance:** No genetically guided drug selection or dosing recommendations are available. **Polypharmacy guidance:** clonazepam is extensively metabolized by CYP3A4 to an amino metabolite that is further acetylated by N-acetyltransferases. This drug should be used with caution when prescribed with CYP3A4 inhibitors or inducers.

## Normal Exposure to Clonidine

**Pharmacogenetic guidance**: Clonidine is metabolized by CYP2D6 along with CYP3A4 and CYP1A2. About 40-60% of the dose is excreted in urine as unchanged drug. Preliminary studies indicate that individuals lacking CYP2D6 activity, have increased clonidine exposure compared to subjects with normal CYP2D6 activity. The clinical relevance of this changed is not well understood and there is insufficient data to calculate dose adjustments. Other preliminary studies indicate that individuals with high CYP2D6 activity (pregnant women), have decreased clonidine exposure and may require higher doses to reach target therapeutic plasma concentrations and respond to therapy. No genetically guided drug selection or dosing adjustments are recommended. **Polypharmacy guidance**: Co-administration of clonidine with inhibitors of CYP2D6 or CYP3A4 may cause an increase in clonidine plasma concentrations. Caution should be used when co-administering drugs that can affect renal function.

Codeine can be prescribed at standard label-recommended age- or we	ight-based dosing and monitoring.				
Normal Response to Colchicine	INFORMATIVE				
<b>Pharmacogenetic guidance:</b> Colchicine in eliminated both by renal excretion and metabolism. While 50% of the absorbed dose is eliminated unchanged in urine, less than 20% is metabolized by CYP3A4. Glucuronidation is also a metabolic pathway for colchicine. Colchicine is a substrate of P-glycoprotein (encoded by ABCB1 gene) and its efflux by this transporter is important in its disposition. Colchicine has a narrow therapeutic index. Preliminary and limited studies indicate a lack of an effect of CYP3A4 or ABCB1 genetic polymorphisms on clinical response to colchicine in individuals with familial Mediterranean fever (FMF). There are no available genetically-guided drug selection or dosing recommendations. <b>Polypharmacy guidance:</b> Because colchicine is a substrate for both the CYP3A4 metabolizing enzyme and the P-glycoprotein efflux transporter, inhibition of either of these pathways may lead to colchicine-related toxicity. Inhibition of both CYP3A4 and P-gp by dual inhibitors such as clarithromycin has been reported to produce life-threatening or fatal colchicine toxicity due to significant increases in systemic colchicine levels. Therefore, concomitant use of colchicine and inhibitors of CYP3A4 or P-glycoprotein should be avoided.					
Normal Response to Cyclobenzaprine	INFORMATIVE				
<b>Pharmacogenetic guidance:</b> No genetically guided drug selection or Cyclobenzaprine is excreted primarily as a glucuronide via the kidneys, CYP1A2, and to a lesser extent CYP2D6. Due to the minor involvement the polymorphism of this enzyme is not of concern in its the clinical us	and as an N-demethylated metabolite by CYP3A4, of CYP2D6 in the metabolism of cyclobenzaprine,				
Normal Response to Dabigatran	INFORMATIVE				
<b>Pharmacogenetic guidance:</b> Dabigatran is eliminated primarily uncha dabigatran etexilate is converted to its active form dabigatran by ester					

Pharmacogeneti dabigatran etexilate is converted to its active form dabigatran by esterases. A small portion (20%) of dabigatran dose is also conjugated to form pharmacologically active acyl glucuronides. Dabigatran is not a substrate, inhibitor, or inducer of CYP450 enzymes. Dabigatran etexilate is a substrate of the efflux transporter P-gp (ABCB1). Common genetic polymorphism of the ABCB1 gene (2677G>T/A and 3435 C>T) do not appear to affect dabigatran exposure. Polypharmacy guidance: <u>1-Reduction in Risk of Stroke and Systemic Embolism in Non-valvular AF</u>: In patients with moderate renal impairment (CrCl 30-50 mL/min), concomitant use of the P-gp inhibitor dronedarone or systemic ketoconazole can be expected to produce dabigatran exposure similar to that observed in severe renal impairment. Consider reducing the dose of dabigatran to 75 mg twice daily. Dose adjustment is not necessary when coadministered with other P-gp inhibitors. In patients with CrCl<30 mL/min, avoid use of concomitant P-gp inhibitors with dabigatran. 2-Treatment of DVT and PE Reduction in the Risk of Recurrence of DVT and PE: Avoid use of concomitant P-gp inhibitors with dabigatran in patients with CrCl <50 mL/min.

Pharmacogenetic guidance: Fosaprepitant is a prodrug of aprepitant which is rapidly converted to aprepitant following

DATE: TE: : 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

intravenous administration. Its antiemetic effects are attributable to aprepitant. Aprepitant undergoes extensive metabolism via N- and O-dealkylations. These pathways are primarily catalyzed by CYP3A4 with minor involvement from CYP1A2 and CYP2C19. The drug is also glucuronidated by UGT1A4 and UGT1A3. No genetically guided drug selection or dosing recommendations are available. Polypharmacy Guidance: In presence of moderate and strong CYP3A4 inhibitors, a significantly increased exposure of aprepitant is expected which may lead to adverse reactions. These drugs should be avoided with fosaprepitant. Strong CYP3A4 inducers can significantly decrease aprepitant exposure resulting in a loss of efficacy. These drugs should also be avoided with fosaprepitant. Aprepitant is a moderate (dose-dependent) inhibitor, and an inducer of CYP3A4 and an inducer of CYP2C9. Some substrates of these enzymes are contraindicated with fosaprepitant while others should be closely monitored and their doing adjusted when coadministered with this antiemetic medication. INFORMATIVE Fosnetupitant / Normal Response to Fosnetupitant-Palonosetron (CYP2D6: Normal Metabolizer) Palonosetron Fosnetupitant: Fosnetupitant is converted to netupitant via metabolic hydrolysis. Netupitant is extensively metabolized to Akynzeo-IV® three major metabolites (desmethyl, N-oxide and a hydroxy-methyl derivatives). Metabolism is mediated primarily by CYP3A4 and to a lesser extent by CYP2C9 and CYP2D6. No genetically guided drug selection or dosing recommendations are available for this drug. Fosnetupitant can be prescribed at standard label-recommended dosage and administration. Palonosetron: Palonosetron can be prescribed at standard label-recommended dosage and administration. Normal Phenytoin (Fosphenytoin Active Metabolite) Exposure (CYP2C9: Normal ACTIONABLE Fosphenytoin Metabolizer) Cerebyx<sup>®</sup> Fosphenytoin is a prodrug of phenytoin. The genotype results indicate that the patient is expected to have a normal CYP2C9 enzyme activity. Fosphenytoin can be prescribed at a standard loading dose and a standard maintenance dose. Consider therapeutic drug monitoring and evaluate the patient's response to optimize the maintenance dosage. Gabapentin INFORMATIVE Normal Response to Gabapentin Pharmacogenetic guidance: no genetically guided drug selection or dosing recommendations are available. Neurontin<sup>®</sup> Polypharmacy guidance: Gabapentin is eliminated primarily through renal excretion and is not metabolized by CYPs. Genetic variations in these metabolizing enzymes are not expected to affect its efficacy or toxicity profiles. Gabapentin can be prescribed at standard label-recommended dosage and administration. Galantamine Normal Sensitivity to Galantamine (CYP2D6: Normal Metabolizer) INFORMATIVE Razadyne<sup>®</sup> Galantamine can be prescribed at standard label-recommended dosage and administration. Individualization of dose with weekly titration is recommended. Glimepiride Normal Exposure to Glimepiride ACTIONABLE Pharmacogenetic guidance: Glimepiride is metabolized by CYP2C9. While this clearance pathway is diminished in **Amaryl**® subjects with reduced CYP2C9 activity, such a change has not been shown to be clinically significant. No genetically guided drug selection or dosing adjustments are recommended. Polypharmacy guidance: Co-administration of glimepiride with a strong CYP2C9 inhibitor may result in higher glimepiride concentrations possibly leading to hypoglycemia. Co-administration with a strong CYP2C9 inducer may result in lower glimepiride concentrations and a lack of efficacy. INFORMATIVE Glipizide Normal Exposure to Glipizide Pharmacogenetic guidance: Glipizide is metabolized by CYP2C9. While this clearance pathway is diminished in subjects Glucotrol® with reduced CYP2C9 activity, such a change has not been shown to be clinically significant. No genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: Co-administration of glipizide with a strong CYP2C9 inhibitor may result in higher glipizide concentrations possibly leading to hypoglycemia. Coadministration with a strong CYP2C9 inducer may result in lower glipizide concentrations and a lack of efficacy. SPECIMEN DETAILS

SPECIMEN TYPE:

ORDERED BY

COLLECTION DATE: DOB: **RECEIVED DATE:** SEX: REPORT DATE: 11/11/2022 FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE Pharmacogenetic guidance: Genotype results obtained from the pharmacogenetic test performed in this patient cannot be used to identify patients at risk for severe cutaneous adverse reactions such as anticonvulsant hypersensitivity syndrome, Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN). Lamotrigine is metabolized by glucuronidation, which is mediated primarily by UGT1A4 with some contribution from UGT1A1 and UGBT2B7. There are insufficient studies documenting the impact of genetic polymorphisms of these metabolizing enzymes on lamotrigine response. No genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: Enzyme-inducing drugs increase lamotrigine clearance significantly, and higher doses of this drug are required to maintain therapeutic concentrations. Coadministration of valproic acid, an inhibitor of UGT enzymes, increases lamotrigine levels and may result in serious lamotrigine adverse effects (neurological and cutaneous). A low starting dose with a slow titration schedule is recommended when lamotrigine is added to existing valproic acid treatment. Leflunomide INFORMATIVE Normal Exposure to Leflunomide (CYP2C19: Rapid Metabolizer) Leflunomide can be prescribed according to standard label-recommended dosage and administration. Arava ® Full blood cell count (CBC) and liver function parameters should be checked no more than 6 months before beginning treatment, and every month for the initial 6 months of therapy. Blood pressure should be checked before beginning treatment and periodically thereafter. INFORMATIVE Levetiracetam Normal Response to Levetiracetam Keppra® Pharmacogenetic guidance: No genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: Levetiracetam is minimally metabolized by non-CYP enzymes (esterases) and is primarily excreted unchanged in urine. Coadministration of enzyme-inducing antiepileptic drugs produce modest decreases in levetiracetam plasma levels. INFORMATIVE Levomilnacipran Normal Response to Levomilnacipran Pharmacogenetic guidance: Levomilnacipran is moderately metabolized by desethylation, which is catalyzed primarily Fetzima® by CYP3A4, with minor contributions by CYP2C8, CYP2C19, CYP2D6, and CYP2J2. More than 58% of the dose is excreted in urine as unchanged levomilnacipran, and 18% as N-desethyl levomilnacipran. Genetic polymorphisms of CYPs are not expected to have a significant impact on levomilnacipran exposure. no genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: the daily levomilnacipran dose should not exceed 80 mg when coadministered with strong CYP3A4 inhibitors, such as ketoconazole, itrazonazole, and ritonavir. Levorphanol INFORMATIVE Normal Response to Levorphanol Pharmacogenetic guidance: Levorphanol is metabolized by glucuronidation which is mediated by UGT2B7. There are no Levo Dromoran® studies documenting the impact of genetic polymorphisms of this metabolizing enzyme on levorphanol response. And no genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: Enzyme inducing drugs are expected to increase levorphanol clearance significantly. Lisdexamfetamine Normal Exposure to Lisdexamfetamine (CYP2D6: Normal Metabolizer) INFORMATIVE Vvvanse<sup>®</sup> Lisdexamfetamine can be prescribed at standard label-recommended dosage and administration. Individualize the dosage according to the therapeutic needs and response of the patient. Lisdexamfetamine Good Response to Lisdexamfetamine (COMT: Intermediate COMT Activity) INFORMATIVE Vyvanse<sup>®</sup> The patient's genotype result predicts a favorable response to amphetamine stimulants. Lisdexamfetamine should be administered at the lowest effective dose, and dosage should be individually adjusted. ACTIONABLE Lofexidine Normal Exposure to Lofexidine (CYP2D6: Normal Metabolizer) Lofexidine is metabolized by CYP2D6 with contributions from CYP2C19 and CYP1A2. The genotype results predict that Lucemyra<sup>®</sup> the patient is expected to have a normal clearance and a typical exposure to this drug. Use label-recommended dosage and follow standard precautions.

SPECIMEN DETAILS

SPECIMEN TYPE: COLLECTION DATE: ORDERED BY

**RECEIVED DATE:** SEX: REPORT DATE: 11/11/2022 FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE INFORMATIVE **Phenobarbital** Normal Sensitivity to Phenobarbital (CYP2C19: Rapid Metabolizer) Luminal® CYP2C19 is partly involved in the metabolism of phenobarbital, and this drug can be prescribed at standard labelrecommended dosage and administration. ACTIONABLE Phenytoin Normal Phenytoin Exposure (CYP2C9: Normal Metabolizer) Dilantin<sup>®</sup> The genotype results indicate that the patient is expected to have a normal CYP2C9 enzyme activity. Phenytoin can be prescribed at a standard loading dose and a standard maintenance dose. Consider therapeutic drug monitoring and evaluate the patient's response to optimize the maintenance dosage. Pimavanserin INFORMATIVE Normal Response to Pimavanserin Pharmacogenetic guidance: Pimavanserin is predominantly metabolized by CYP3A4 and CYP3A5 and to a lesser extent Nuplazid® by CYP2J2, CYP2D6, and other CYP and FMO enzymes. CYP3A4 is the major enzyme responsible for the formation of its major active metabolite (AC-279). There are no available genetically-guided drug selection or dosing recommendations. Polypharmacy guidance: Pimavanserin prolongs the QT interval and its use should be avoided in patients with known QT prolongation or in combination with other drugs known to prolong QT interval including Class 1A antiarrhythmics (e.g., quinidine, procainamide) or Class 3 antiarrhythmics (e.g., amiodarone, sotalol), certain antipsychotic medications (e.g., ziprasidone, chlorpromazine, thioridazine), and certain antibiotics (e.g., gatifloxacin, moxifloxacin). Concomitant use of pimavanserin with CYP3A4 inhibitor increases pimavanserin exposure and a dose reduction of 50% is needed when this drug is coadministered with strong CYP3A inhibitors. Coadministration of pimavanserin with strong CYP3A inducers may result in reduced efficacy and a dose increase may be needed. Pimozide ACTIONABLE Normal Exposure to Pimozide (CYP2D6: Normal Metabolizer) Consider prescribing pimozide at standard label-recommended dosage and administration. Standard starting dose: 1 to 2 Orap<sup>®</sup> mg/day. Doses may be increased to a maximum of 10 mg/day. Concomitant use of pimozide with strong CYP2D6 or strong CYP3A inhibitors is contraindicated. Cautions should be taken when pimozide is administered with other drugs that prolong QT. **Piroxicam** Normal Piroxicam Exposure (CYP2C9: Normal Metabolizer) ACTIONABLE Rheumatoid Arthritis and Osteoarthritis: Piroxicam therapy can be initiated at standard label-recommended dosage Feldene® and administration. Consider using the lowest effective dosage for the shortest duration consistent with the patient treatment goals. Consider initiating treatment at the lowest end of the dosing range in geriatric patients. A dosage adjustment may be warranted when piroxicam is administered with CYP2C9 inhibitors or inducers. Pitavastatin Normal Pitavastatin Exposure (SLCO1B1: Normal Function) ACTIONABLE Livalo<sup>®</sup> Pitavastatin can be prescribed at standard label-recommended dosage and administration. Posaconazole ACTIONABLE Normal Response to Posaconazole Pharmacogenetic guidance: Posaconazole is cleared primarily as unchanged drug. The excreted metabolites in urine Noxafil<sup>®</sup> and feces account for approximately 17% of the administered dose. The metabolic pathways for posaconazole include direct glucuronidation, minor oxidation and dealkylation. CYP3A4 (and possibly CYP1A1 and CYP3A5), UGT1A4, and Pglycoprotein are enzymes and transporters that play a role in the elimination of this antifungal. No genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: UGT and P-glycoprotein inhibitors or inducers may affect posaconazole plasma concentrations. Concomitant use of posaconazole and these agents should be avoided unless the benefit to the patient outweighs the risk. ACTIONABLE Prasugrel Normal Response to Prasugrel Genetic Test Results For Patient io284w9 Translational

<b>√</b>	<b>Pravastatin</b> Pravachol®	Normal Pravastatin Exposure (SLCO1B1: Normal Function)       ACTIONA         Pravastatin can be prescribed at standard label-recommended dosage and administration.				
✓	<b>Pregabalin</b> Lyrica®	Normal Response to Pregabalin       INFORMATIVE         Pharmacogenetic guidance:       No genetically guided drug selection or dosing recommendations are available.         Polypharmacy guidance:       Pregabalin is eliminated primarily through renal excretion and is not metabolized by CYPs.         Genetic variations in these metabolizing enzymes are not expected to affect its efficacy or toxicity profiles. Pregabalin can be prescribed at standard label-recommended dosage and administration.				
√	<b>Primidone</b> Mysoline®	Normal Sensitivity to Primidone (CYP2C19: Rapid Metabolizer) INFORM CYP2C19 is partly involved in the metabolism of phenobarbital, the active metabolite of primidone, and this drug car prescribed at standard label-recommended dosage and administration.				
✓	<b>Proguanil</b> Malarone®	Normal Exposure to Proguanil Information INFORMATIV Pharmacogenetic guidance: Proguanil is a pro-drug that is primarily metabolized by CYP2C19 to its active metabolite, cycloguanil. Preliminary studies indicate that individuals with reduced CYP2C19 function, have reduced cycloguanil exposure compared to subjects with normal CYP2C19 function, but there is considerable overlap of cycloguanil and proguanil metabolic ratios across CYP2C19 metabolizer status. The clinical relevance of this change is not well understoo and there is insufficient data to calculate dose adjustments. No genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: Co-administration of proguanil with a strong CYP2C19 inhibitor may result in lower cycloguanil (higher proguanil) exposure.				
<b>√</b>	<b>Propafenone</b> <i>Rythmol</i> ®	The patient's genot prescribing propafe with ECG monitorin <b>Dose adjustments</b> inhibitors may signi other adverse event	none at standard label-recomm g until a favorable response is a with co-medications: concurre ficantly increase the plasma cor	propafenone exposure following s ended dosage and administration	. 	Ranolazine	Normal Sensitivit	ty to Ranolazine (CYP2D6: N	lormal Metabolizer)		ACTIONABL	
-	Ranexa®	Ranolazine is metabolized mainly by CYP3A4, and to a lesser extent by CYP2D6. This drug can be prescribed at standard label-recommended dosage and administration. The recommended initial dose is 375 mg twice daily. After 2–4 weeks, the dose should be titrated to 500 mg twice daily, and according to the patient's response, further titrated to a recommended maximum dose of 1000 mg twice daily.					
		If patient experiences treatment-related adverse events (e.g. dizziness, nausea, vomiting, or syncope), down titration of ranolazine to 500 or 375 mg twice daily may be required. If symptoms do not resolve after dose reduction, treatment should be discontinued.					
		<b>Ranolazine is a QTc prolonging drug.</b> Caution should be observed when treating: 1- patients with a history of congenital or a family history of long QT syndrome, 2- patients with known acquired QT interval prolongation, and 3-patients treated with drugs affecting the QTc interval. Administration of CYP3A4 inhibitors increases the exposure of ranolazine significantly. As a consequence, the QTc prolongation by ranolazine in the presence of potent CYP3A inhibitor is significantly elevated relative to when the drug is administered alone.

ACTIONABLE

SPECIMEN TYPE: COLLECTION DATE: **RECEIVED DATE:** REPORT DATE: 11/11/2022

INFORMATIVE Trifluoperazine Normal Response to Trifluoperazine Pharmacogenetic guidance: Thrifluoperazine extensively metabolized by oxidation, sulfoxidation, hydroxylation and Stelazine® direct glucuronidation catalyzed by UGT1A4. No genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: It is likely that strong enzyme inducers may lead to substantial decreases in trifluoperazine plasma concentrations with the potential for reduced effectiveness. Trospium INFORMATIVE Normal Response to Trospium Sanctura® Pharmacogenetic guidance: no genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: CYP enzymes do not contribute significantly to the elimination of trospium. No major drugdrug interactions are expected with CYP inhibitors or inducers. Valbenazine Normal Sensitivity to Valbenazine (CYP2D6: Normal Metabolizer) Valbenazine can be prescribed at standard label-recommended dosage and administration. The initial dose is 40 mg once Ingrezza® daily which can be increased after a week of therapy to the recommended dose of 80 mg once daily. Dose adjustments with comedications: reduce the daily recommended dose to 40 mg if a strong CYP3A4 inhibitor is coadministered. In presence of a CYP2D6 inhibitor, the daily recommended dose may be reduced based on tolerability. Concomitant use with CYP3A4 inducers should be avoided. Valproic Acid INFORMATIVE Normal Response to Valproic acid Depakene<sup>®</sup> Pharmacogenetic guidance: Genotype results obtained from the pharmacogenetic test performed in this patient cannot be used to identify patients carrying mutations in mitochondrial DNA polymerase y (POLG). Valproic acid is contraindicated in patients known to have mitochondrial disorders caused by mutations in mitochondrial DNA polymerase y (POLG; e.g., Alpers-Huttenlocher Syndrome) and children under two years of age who are suspected of having a POLG-related disorder. Valproic acid is extensively metabolized in the liver, which occurs primarily by glucuronidation with probable contributions of UGT1A6, UGT1A9, and UGT2B7. This drug is also metabolized by a minor CYP-dependent oxidation pathway, which includes multiple enzymes such as CYP2A6, CYP2C9, and CYP2C19. There are insufficient studies documenting the impact of genetic polymorphisms of these metabolizing enzymes on valproic acid response, and no genetically guided drug selection or dosing recommendations are available. Polypharmacy guidance: enzyme-inducing drugs increase valproic acid clearance 2-fold, and higher doses of this drug are required to maintain therapeutic concentrations when added to a therapy regimen containing enzyme-inducing antiepileptic drugs. Valsartan Normal Sensitivity to Valsartan Diovan<sup>®</sup>, Entresto<sup>®</sup> Pharmacogenetic guidance: Valsartan is excreted largely as unchanged compound. CYP2C9 is responsible for the formation of a minor metabolite, valeryl 4-hydroxy valsartan, which accounts for about 9% of a dose. Given the limited contribution of CYP2C9 in the overall disposition of valsartan, genetic variability of the CYP2C9 gene is not expected to affect the patient's response to valsartan. No genotype-based dosing adjustments are available. Vardenafil Normal Response to Vardenafil Pharmacogenetic guidance: Preliminary findings indicate that vardenafil exposure is 3 times higher in individuals with Levitra<sup>®</sup> CYP3A5\*3/\*3 genotype compared to those with CYP3A5\*1/\*1 genotype. The clinical impact of this change is unknown. Polypharmacy guidance: The dosage of vardenafil may require adjustment in patients receiving strong CYP3A4 inhibitors such as ketoconazole, itraconazole, ritonavir, indinavir, saquinavir, atazanavir, or clarithromycin, as well as in patients receiving moderate CYP3A4 inhibitors such as erythromycin. For ritonavir, a single dose of 2.5 mg vardenafil should not be exceeded in a 72-hour period. For indinavir, saquinavir, atazanavir, or ketoconazole: 400 mg daily. For itraconazole: 400 mg daily. For clarithromycin: a single dose of 2.5 mg vardenafil should not be exceeded in a 24-hour period. For ketoconazole: 200 mg daily. For itraconazole: 200 mg daily. For erythromycin: a single dose of 5 mg vardenafil should not be exceeded in a 24-hour period. Inducers of CYP3A4 may decrease the concentrations of vardenafil.

SPECIMEN DETAILS

SPECIMEN TYPE: COLLECTION DATE: RECEIVED DATE: REPORT DATE: 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

**Pharmacogenetic guidance:** Ziprasidone is primarily cleared following extensive metabolism. CYP3A4 is the major CYP contributing to the oxidative metabolism of ziprasidone with minor involvement from CYP1A2. Less than one-third of ziprasidone metabolic clearance is mediated by cytochrome P450 catalyzed oxidation and approximately two-thirds via reduction involving glutathione as well as aldehyde oxidase. No genetically guided drug selection or dosing recommendations are available. Individualization of ziprasidone dose with careful weekly titration is required. Dosage adjustments should generally occur at intervals of no less than 2 days, as steady-state plasma concentrations are achieved within 1 to 3 days. In order to ensure use of the lowest effective dose, patients should ordinarily be observed for improvement for several weeks before upward dosage adjustment. When deciding among the alternative treatments available, the prescriber should consider the finding of **ziprasidone's greater capacity to prolong the QT/QTc interval** compared to several other antipsychotic drugs. **Polypharmacy guidance:** Although coadministration of strong CYP3A4 inhibitors are expected to result in modest increases in ziprasidone plasma concentrations, a closer monitoring of the patient's response and a dose reduction may be considered. Ziprasidone dose may need to be increased when used in combination with a chronic treatment of a potent CYP3A4 inducer (e.g., phenytoin, carbamazepine, rifampin, St. John's wort etc.).

#### Normal Sensitivity to Zonisamide (CYP2C19: Rapid Metabolizer)

INFORMATIVE

CYP2C19 is partly involved in the metabolism of zonisamide, and this drug can be prescribed at standard label-recommended dosage and administration.

Limitation: This test will not detect all the known alleles that result in altered or inactive tested genes. This test does not account for all individual variations in the individual tested. Absence of a detectable gene mutation does not rule out the possibility that a patient has different phenotypes due to the presence of an undetected polymorphism or due to other factors such as drug-drug interactions, comorbidities and lifestyle habits.

Methodology: Array based assays detect listed alleles, including all common and most rare variants with known clinical significance at analytical sensitivity and specificity >99%.

Disclaimer: Manchester University developed the Genotype test. The performance characteristics of this test were determined by Manchester University. It has not been cleared or approved by the U.S. Food and Drug Administration.

Translational Software Disclaimer: The information presented on this report is provided as general educational health information. The content is not intended to be a substitute for professional medical advice, diagnosis, or treatment. Only a physician, pharmacist or other healthcare professional should advise a patient on the use of the medications prescribed.

The pharmacogenetic assay involves use of reporting software and genotype-phenotype associations performed by Translational Software (www.translationalsoftware.com). The software has not been evaluated by the Food and Drug Administration. The software, and the report generated by the software, is not intended to diagnose, treat, cure, or prevent any disease. A qualified designee within the lab uses Translational Software to generate and subsequently review the report. The pharmacogenetic report is one of multiple pieces of information that clinicians should consider in guiding their therapeutic choice for each patient. It remains the responsibility of the health-care provider to determine the best course of treatment for a patient. Adherence to dose guidelines does not necessarily assure a successful medical outcome.

## **APOE Monograph**

### **Clinical Utility**

Apolipoproteins (APO) are structural constituents of lipoprotein particles that have critical roles in blood lipid metabolism and transport. Apolipoprotein E (APOE) is a major constituent of triglyceride-rich chylomicrons, very low-density lipoproteins (VLDL), and some subclasses of high-density lipoproteins (HDL). APOE acts as a lipid carrier and transports cholesterol from the cells in the blood vessel wall to the liver for excretion. It also binds to several cell surface receptors to support membrane homeostasis and injury repair in the brain. Defects in APOE can result in hyperlipidemia, which is an important risk factor in the genesis of atherosclerosis and subsequent development of cardiovascular disease (CVD).

#### **Assay Interpretation**

There are three common APOE alleles designated  $\epsilon_2$ ,  $\epsilon_3$ , and  $\epsilon_4$ , resulting from combinations of the two common variants c.388T>C (rs429358, p.Cys130Arg) and c.526 C>T (rs7412, p.Arg176Cys). These alleles result in E2, E3, and E4 protein isoforms, respectively. The approximate allele frequencies for most populations are 8-12% for  $\epsilon_2$ , 74-78% for  $\epsilon_3$ , and 14-15% for  $\epsilon_4$ .

## The reference ranges for both mutations of APOE are c.388T/T and c.526C/C. This is consistent with a ɛ3/ɛ3 genotype and a normal APOE function.

**Clinical Implications**

SPECIMEN DETAILS

ORDERED BY

SPECIMEN TYPE: COLLECTION DATE: RECEIVED DATE: REPORT DATE: 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

The apolipoprotein E3 is considered the normal isoform and is associated with normal lipid metabolism. The apolipoprotein E2 isoform shows defective binding of remnants to hepatic lipoprotein and delayed clearance from plasma. It is associated with a slower conversion of intermediate-density lipoproteins (IDL) to low-density lipoproteins (LDL), lower cholesterol, and higher triglycerides, compared to the normal apolipoprotein E3 isoform. The apolipoprotein E4 isoform results in the down regulation of the LDL receptor and is associated with increased total cholesterol, triglycerides, and LDL.

#### 1 - Type III Hyperlipoproteinemia

<u>Result Interpretation</u>: APOE genotyping can be used to confirm the diagnosis of suspected type III hyperlipoproteinemia. Patients with symptoms (xanthomas) and with a lipid profile consistent with type III hyperlipidemia are candidates for APOE genotype analysis. Homozygosity for the APOE  $\epsilon^2$  allele is strongly associated with type III hyperlipoproteinemia. Over 90% of individuals presenting the clinical type III hyperlipoproteinemia have the rare  $\epsilon^2/\epsilon^2$  genotype. These individuals have an increased risk of premature vascular disease.

Only 1-5% of individuals with the APOE  $\epsilon^2/\epsilon^2$  genotype develop type III hyperlipoproteinemia, suggesting that other genetic, hormonal, or environmental factors must contribute the expression of this disease. Despite the accumulation of remnants in the circulation, most (>95%) APOE  $\epsilon^2$  homozygous subjects are normolipidemic or even hypolipidemic because of low LDL cholesterol levels. Other non- $\epsilon^2/\epsilon^2$  APOE genotypes ( $\epsilon^3/\epsilon^3$ ,  $\epsilon^2/\epsilon^3$ ,  $\epsilon^2/\epsilon^4$ ,  $\epsilon^3/\epsilon^4$ ,  $\epsilon^4/\epsilon^4$ ) are not associated with type III hyperlipoproteinemia.

Summary: patients with a lipid profile (tendinous/tuberous xanthomas, elevated cholesterol, triglycerides, very low density lipoprotein (VLDL)) consistent with type III hyperlipoproteinemia are candidates for APOE genotyping. Most patients with type III hyperlipoproteinemia are homozygous for the APOE  $\epsilon^2$  allele and homozygosity for  $\epsilon^2$  allele is the only genotype associated with type III hyperlipoproteinemia. Factors in addition to the defective receptor binding activity of the apolipoprotein E2 isoform are necessary for manifestation of this disorder and only 1-5% of APOE  $\epsilon^2$  homozygous develop type III hyperlipoproteinemia.

#### 2 - Atherosclerotic Cardiovascular Disease

<u>Result Interpretation</u>: genetic testing of APOE genotyping has been proposed for individual cardiovascular risk assessment and/or to predict the response to statin therapy. APOE genotyping can be informative in individuals with premature coronary heart disease or a family history of premature coronary heart disease. The APOE  $\epsilon$ 4 allele has been linked to pure elevations of low-density lipoproteins (LDL), and the  $\epsilon$ 4/ $\epsilon$ 4 and  $\epsilon$ 3/ $\epsilon$ 4 genotypes are associated with increased serum cholesterol levels.

Although the evidence is not fully consistent, it has been estimated that having the  $\epsilon 3/\epsilon 4$  or  $\epsilon 4/\epsilon 4$  genotype is associated with on average a 30 -40% increased risk of cardiovascular disease relative to the common  $\epsilon 3/\epsilon 3$  genotype.

There is some evidence that having an  $\epsilon^2/\epsilon^2$  or  $\epsilon^2/\epsilon^3$  genotype may be associated with a lower CVD risk in Caucasians normolipidemic patients. A proposed explanation of such observation is the association between APOE2 allele and lower Lp(a) concentrations.

Summary: the APOE  $\epsilon$ 4 allele results in the down regulation of the LDL receptor and is associated with increased total cholesterol, triglycerides, and LDL. Several studies indicate that the  $\epsilon$ 3/ $\epsilon$ 4,  $\epsilon$ 2/ $\epsilon$ 4 or  $\epsilon$ 4/ $\epsilon$ 4 genotypes are associated with increased plasma cholesterol levels. The presence of the  $\epsilon$ 3/ $\epsilon$ 4 or  $\epsilon$ 4/ $\epsilon$ 4 genotype has been suggested as a risk factor for atherosclerosis and coronary heart disease. Thus, the APOE genotype may be useful and informative in individuals with a family history of coronary heart disease as an additional tool for assessing their risk in conjunction with other clinical or laboratory findings. No clinical practice guidelines or position statements from U.S. professional associations were identified that recommended the use of APOE genotyping in cardiovascular risk assessment, including but not limited to the following: the 2013 American College of Cardiology/American Heart Association guidelines for the assessment of cardiovascular risk in asymptomatic patients; the 2009 U.S. Preventive Services Task Force (USPSTF) recommendations on the use of nontraditional risk factors for the assessment of coronary heart disease; the American Diabetes Association and the American College of Cardiology Foundation consensus conference publication.

## **COMT Monograph**

#### **Clinical Utility**

Catechol-O-Methyltransferase (COMT) is an enzyme responsible for the metabolism of catecholamines and catechol-estrogens in the central nervous system and other organs. Dopamine is cleared mainly by COMT in the frontal cortex, and a reduced activity of this enzyme results in higher synaptic levels of dopamine, which affects prefrontal cortex cognitive response to certain drugs. A single nucleotide polymorphism of the COMT gene produces an amino acid change from valine to methionine (Val158Met) and reduces the enzyme activity by 3- to 4-fold.

#### **Assay Interpretation**

The most well studied COMT genetic variant (rs4680; 472G>A) is the one resulting in a valine to methionine change at codon 158. The variant allele called the Met allele is found in 30-47% of Caucasians, 23% of Africans, and 27-32% of Asians. The phenotype is defined by the presence of the reduced activity Met allele (A variant). The wild-type genotype (Val/Val; GG) predicts a high/normal COMT activity, the heterozygous genotype (Val/Met; GA) predicts an intermediate COMT activity, and the homozygous (Met/Met; AA) results in a low COMT activity.

# The reference range for COMT metabolic status is COMT Val158Met GG (Val/Val) (wild-type), which is consistent with a high/normal COMT activity.

#### **Clinical Implications**

Several complex associations with the Val158Met variant as a risk factor for numerous diseases have been found, but seem to have limited predictive value. The response to some psychotropic medications seems to be dependent to some extent upon the COMT status. In general, the wild-type genotype result predicts a good response to methylphenidate and amphetamines in the treatment of attention deficit hyperactivity disorder. In the treatment of pain, patients who are homozygous for the Met allele require lower doses of morphine to achieve analgesia.

### CYP1A2 Monograph

#### **Clinical Utility**

The cytochrome P450 1A2 (CYP1A2) accounts for 13% of total CYP in the human liver, and is responsible for metabolizing 8-10% of commonly used drugs as well as natural compounds such as caffeine. A large inter-individual variability in the elimination of drugs that are metabolized by CYP1A2 has been observed, which has been ascribed to genetic variations and environmental factors. CYP1A2 activity is highly inducible (increased) by environmental factors including smoking (tobacco), some drugs, and several dietary compounds (cruciferous vegetables).

#### **Assay Interpretation**

More than 20 different alleles have been characterized for the CYP1A2 gene, and some have been shown to affect enzyme activity and its sensitivity towards inducers (inducibility). The CYP1A2\*1F is the most studied allele and results in a rapid metabolizer phenotype in the presence of inducers, while CYP1A2\*1K and \*1C alleles result in enzymes that are less active and less sensitive to induction. The CYP1A2\*1F allele is found in 25-50% of Caucasians, 30% of Asians, and 50% of Ethiopians. The genotype-phenotype relationship for CYP1A2 is not well established, and can be expressed in terms of metabolic capacity as well as sensitivity towards induction (inducibility). Individuals are predicted to have CYP1A2 normal, intermediate, or poor metabolic capacity, with high, possible, or low inducibility depending on their genotype.

#### The reference range for CYP1A2 metabolic status is CYP1A2 \*1A/ \*1A, which is consistent with a normal metabolizer that is possibly inducible.

#### **Clinical Implications**

CYP1A2 genotype can help identify patients with high or low sensitivity to inducing agents, especially those released during smoking. The clinical relevance of this sensitivity becomes important in patients who are smokers or who quit smoking. Patients with the highly inducible genotype CYP1A2\*1F/\*1F can experience loss of response to drug substrates while they are exposed to dietary or environmental inducers, and therefore may require higher doses.

The following drugs used in the management of pain and various psychiatric conditions are metabolized extensively by CYP1A2 and are sensitive to its function: clozapine (Clozaril), duloxetine (Cymbalta), olanzapine (Zyprexa), and tizanidine (Zanaflex). CYP1A2 also metabolizes other important drugs such as melatonin, ondansetron (Zofran), pirfenidone (Esbriet), pomalidomide (Pomalyst), ramelteon (Rozerem), ropivacaine (Naropin), and tasimelteon (Hetlioz).

CYP1A2 metabolism is highly sensitive to inhibition and induction, and the occurrence of drug-drug interactions can have profound effects on the pharmacokinetics, response, and safety profiles of many CYP1A2 drug substrates.

#### Inhibitors

Some known strong CYP1A2 inhibitors include: ciprofloxacin (Cipro), enoxacin (Penetrex), fluvoxamine (Luvox) and zafirlukast (Accolate).

Some known moderate to weak CYP1A2 inhibitors include: allopurinol (Zyloprim), mexiletine (Mexitil), norfloxacin (Norflox), peginterferon alfa-2a (Pegasys), obeticholic acid (Ocaliva), oral contraceptives, ticlopidine (Ticlid), vemurafenib (Zelboraf) and zileuton (Zyflo).

#### Inducers

Known CYP1A2 inducers include: carbamazepine (Tegretol), montelukast (Singulair), moricizine (Ethmozine), omeprazole (Prilosec), phenobarbital, phenytoin (Dilantin), primidone (Mysoline) and rifampin (Rifadin).

Some dietary and environmental compounds found in charcoal-grilled food, cigarette smoke and cruciferous vegetables can also increase CYP1A2 activity.

## CYP2B6 Monograph

NAME: Patient io284w9 ACC #: io284w9 DOB: 1/1/1900 SEX: SPECIMEN DETAILS

ORDERED BY

SPECIMEN TYPE: COLLECTION DATE: RECEIVED DATE: REPORT DATE: 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

The cytochrome P450 2B6 (CYP2B6) enzyme is responsible for the metabolism of 4% of frequently used medications. It is expressed primarily in the liver and also in the brain. This enzyme is highly polymorphic: to date, a large number of variants have been identified. The CYP2B6 assay identifies some common variants that are associated with variability in enzyme activity, which has important clinical implications for efavirenz dosing.

#### **Assay Interpretation**

Genetic polymorphism in CYP2B6 result in different enzyme isoforms that are fully active (normal function), partially active (decreased function), inactive (no function), or have increased activity (increased function). The CYP2B6\*1 allele is considered wild-type and encodes a functionally active enzyme (normal). Common decreased function alleles include the \*6, \*7, and \*9 alleles. The \*4 and \*22 alleles are increased function alleles while the \*18 allele is a no-function allele. Of note, common functional polymorphisms in CYP2B6 alter enzyme activity in a substrate-dependent manner. For most substrates, activity of the \*9 variant is exceptionally low, activity of the \*4 variant is similar or greater than that of the \*1, while the activity of the \*6 variant lies between \*9 and \*4, depending on substrate.

The most clinically relevant decreased function allele is the CYP2B6\*6 allele. It is found in 7-18%, 10-17%, 23% and 33% of Caucasians, Asians, Mexican-Americans and African-Americans, respectively. The CYP2B6\*18 allele is found only in individuals of African descent, with a frequency of 4-7%.

An individual carrying two normal function alleles is considered a normal metabolizer. An individual carrying one normal function allele and one decreased function allele OR one normal function allele and one no function allele OR one increased function allele and one decreased function allele OR one increased function allele and one no function allele is considered an intermediate metabolizer. An individual carrying two decreased function alleles OR two no function alleles OR one decreased function allele and one no function allele is considered a poor metabolizer. An individual carrying one normal function allele and one increased function allele is considered a rapid metabolizer. An individual carrying two increased function alleles is considered an ultra-rapid metabolizer.

#### The reference range for CYP2B6 metabolic status is CYP2B6 \*1/ \*1, which is consistent with a normal metabolizer.

#### **Clinical Implications**

CYP2B6 plays a role in the metabolism of the following drugs: artemisinin, bupropion (Wellbutrin), cyclophosphamide (Cytoxan), efavirenz (Sustiva), ketamine (Ketalar), meperidine (Demerol), methadone (Dolophine), nevirapine (Viramune), propofol (Diprivan), and selegiline (Eldepryl).

The impact of CYP2B6 polymorphism on pharmacokinetics and clinical response have been documented in adult and pediatric patients taking efavirenz. Patients who are intermediate or poor metabolizers are likely to have higher dose-adjusted trough concentrations of efavirenz following standard treatment when compared with normal metabolizers. Therefore, these patients are subject to increased risk of CNS adverse events. Decreased initial dosage and therapeutic monitoring are recommended for intermediate and poor metabolizers. Patients who are rapid or ultra-rapid metabolizers are likely to have slightly higher efavirenz clearance with no clinically significant effect on efficacy or toxicity. Efavirenz can be initiated with standard dosing for normal, rapid and ultra-rapid metabolizers. Specific dosing strategies for pediatric patients have been published by a panel of experts (Department of Human and Health Services-Panel on Antiretroviral Therapy and Medical Management of Children Living with HIV). These are based and on CYP2B6 genotype, weight, age and comorbidities.

Inhibitors or inducers of the CYP2B6 enzyme may modify its activity and change the patient's metabolizer status. This can result in drug-drug interactions when a drug substrate is prescribed with known CYP2B6 inhibitors or inducers.

#### Inhibitors

Some known CYP2B6 inhibitors include: clopidogrel (Plavix), darunavir (Prezista), prasugrel (Effient), ritonavir (Norvir), thiotepa (Tepadina), ticlopidine (Ticlid) and voriconazole (Vfend).

#### Inducers

Some CYP2B6 inducers include: artemether (Coartem), carbamazepine (Tegretol), dabrafenib (Tafinlar), efavirenz (Sustiva), metamizole, nevirapine (Viramune), phenobarbital, phenytoin (Dilantin), rifampin (Rimactane), ritonavir (Norvir) and St. John's wort.

## CYP2C19 Monograph

#### **Clinical Utility**

The cytochrome P450 2C19 (CYP2C19) is involved in the metabolism of 10% of clinically important medications. This enzyme is highly polymorphic and more than 30 different alleles have been identified in various ethnicities. The CYP2C19 assay identifies common and rare variants that are associated with variability in CYP2C19 enzyme, which has important pharmacological and toxicological implications for antidepressants, benzodiazepines, antiplatelets, and proton-pump inhibitors.

#### **Assay Interpretation**

CYP2C19 enzyme activity defines a normal or abnormal (intermediate, poor, rapid or ultra-rapid) metabolizer status for a given individual. Several variant alleles have been identified and result in different isoforms of the CYP2C19 enzyme that functionally exhibit normal function, reduction function, no function or increased function. The CYP2C19\*1 allele is considered wild-type/reference allele and CYP2C19 \*11, \*13 and \*18 encodes a functionally active enzyme (normal function allele). The alleles \*2, \*3 \*4-\*8, \*22, \*24, and \*35-\*37 encode an inactive enzyme and are referred to as no function alleles while the \*9, \*10, \*16,\*19, \*25 and \*26 alleles are classified as reduced function alleles. The CYP2C19\*17 is an increased function allele.

A new joint statement by the Association for Molecular Pathology (AMP) and the College of American Pathologists (CAP), provides a twotiered classification of CYP2C19 alleles for inclusion during clinical testing. Tier 1 alleles that should be included in all clinical tests, include CYP2C19 \*2, \*3 and \*17. Tier 2 alleles which may also be included in clinical tests include CYP2C19 \*4A, \*4B, \*5, \*6, \*7, \*8, \*9, \*10 and \*35.

The CYP2C19 genotype-phenotype relationship is established based on the allele's function. An Individual with two normal function alleles is considered a normal metabolizer while an individual carrying two no function alleles is considered a poor metabolizer. An individual carrying one normal function allele with one no function allele or one no function allele with one increased function allele is classified as an intermediate metabolizer. Individuals with two increased function alleles are considered ultra-rapid metabolizers and carriers of one increased function allele with one normal function allele are referred to as rapid metabolizers. Because of limited evidence, individuals carrying two decreased function alleles OR those carrying one normal or increased function allele with one decreased function allele are provisionally categorized as intermediate metabolizers.

#### The reference range for CYP2C19 metabolic status is CYP2C19 \*1/\*1 genotype, which is consistent with a normal metabolizer.

#### **Clinical Implications**

SPECIMEN DETAILS

SPECIMEN TYPE: COLLECTION DATE: RECEIVED DATE: REPORT DATE:

**DATE:** 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

There is substantial evidence linking the CYP2C19 polymorphisms to variability in the pharmacological and safety profiles of the following therapies used in psychiatric conditions and pain management: amitriptyline (Elavil), sertraline (Zoloft), clobazam (Onfi), citalopram (Celexa), escitalopram (Lexapro), diazepam (Valium), imipramine (Tofranil), and carisoprodol (Soma). CYP2C19 plays a minor role in the elimination of methadone (Dolophine).

Cardiovascular medications that are metabolized by CYP2C19 include the prodrug clopidogrel (Plavix), propranolol (Inderal), and cilostazol (Pletal). Proton-pump inhibitors such as omeprazole (Prilosec), esomeprazole (Nexium), lansoprazole (Prevacid), dexlansoprazole (Dexilant), and pantoprazole (Protonix) are major substrates of CYP2C19.

Brivaracetam (Briviact) is primarily metabolized by hydrolysis and by hydroxylation. The hydrolysis reaction is mediated by amidase and the hydroxylation is mediated by CYP2C19. Brivaracetam exposure is increased by 22% and 42%, in CYP2C19 intermediate and poor metabolizers, respectively. CYP2C19 poor metabolizers and patients using inhibitors of CYP2C19 may therefore require dose reduction to avoid concentration-dependent toxicity.

CYP2C19 is significantly involved in the metabolism of voriconazole (Vfend) and the disposition of this antifungal is affected by CYP2C19 genetic polymorphisms. The CPIC dosing guideline for voriconazole recommends selecting an alternative agent that is not dependent on CYP2C19 metabolism in adults who are CYP2C19 ultrarapid metabolizers, rapid metabolizers or poor metabolizers. In pediatric patients, an alternative agent should be used in patients who are ultrarapid metabolizers or poor metabolizers.

Inhibitors or inducers of CYP2C19 enzyme may modify its activity and change the patient's metabolizer status. This can result in drug-drug interactions when a drug substrate is prescribed with known CYP2C19 inhibitors or inducers.

#### Inhibitors

Some known CYP2C19 inhibitors include: armodafinil (Nuvigil), delavirdine (Rescriptor), esomeprazole (Nexium), etravirine (Intelence), felbamate (Felbatol), fluconazole (Diflucan), fluoxetine (Prozac), fluvoxamine (Luvox), moclobemide (Manerix), modafinil (Provigil), omeprazole (Prilosec), oxcarbazepine (Trileptal), ticlopidine (Ticlid), topiramate (Topamax) and voriconazole (Vfend).

#### Inducers

Some known CYP2C19 inducers include: apalutamide (Erleada), artemether (Coartem), carbamazepine (Tegretol), efavirenz (Sustiva), enzalutamide (Xtandi), fosphenytoin (Cerebyx), phenobarbital, phenytoin (Dilantin), primidone (Mysoline), rifampin (Rifadin) and St. John's wort.

SPECIMEN TYPE: COLLECTION DATE: RECEIVED DATE: REPORT DATE: 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

CYP2C9 enzyme activity defines a normal or abnormal (intermediate and poor) metabolizer status for a given individual. Several variant alleles have been identified and result in different CYP2C9 isoforms that functionally are fully active, partially active, or inactive. The CYP2C9 \*1 (wildtype) and CYP2C9\*9 alleles encode functionally active enzymes. A number of CYP2C9 alleles such as \*2, \*4, \*5, \*8, \*11, \*12 and \*31 encode partially active enzymes and are classified as decreased function alleles. Other CYP2C9 alleles such as \*3, \*6, \*13, \*15 and \*25 are considered no -function alleles encoding inactive enzymes. Many other alleles with an unknown/uncertain functional effect have also been identified and can be revealed from testing.

A new joint statement by the Association for Molecular Pathology (AMP) and the College of American Pathologists (CAP), provides a twotiered classification of CYP2C9 alleles for clinical testing. Tier 1 alleles that should be included in all tests, these include CYP2C9 \*2, \*3, 5. \*6, \*8 and \*11. Tier 2 alleles which may also be included in clinical tests include CYP2C9 \*12, \*13 and \*15.

The genotype-phenotype relationship is established based on the allele's function. Individuals with two normal function alleles are considered normal (extensive) metabolizers (AS = 2.0). Individuals with one normal function allele with one decreased function allele are considered intermediate metabolizers (AS = 1.5). Individuals with one normal function allele and one no-function allele or two decreased function alleles are considered intermediate metabolizers (AS = 1.5). Individuals with one normal function allele and one no-function allele or two decreased function alleles are considered intermediate metabolizers (AS = 1.5). Individuals with one decreased function allele and one no function allele are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). Individuals with two no-function alleles are considered poor metabolizers (AS = 0.5). The phenotype of carriers of one or two CYP2C9 unknown/uncertain function alleles cannot be predicted accurately (unknown phenotype).

## The reference range for CYP2C9 metabolic status is CYP2C9 \*1/\*1 genotype, which is consistent with an AS of 2.0 and a normal metabolizer.

#### **Clinical Implications**

Abnormal CYP2C9 activity affects the therapeutic outcome of a variety of drugs used to treat cardiovascular and other conditions. Following the administration of drug substrates, the clinical manifestation in a poor or an intermediate metabolizer depends on the characteristics of the drug (i.e., the amount of drug/metabolites that is cleared by the enzyme), and the safety and pharmacological profiles of the drug and its metabolites. Within the medications used to treat cardiovascular conditions, there is compelling evidence that the response to certain angiotensin II inhibitors, statins, and anticoagulants is altered in individuals exhibiting abnormal CYP2C9 activity.

CYP2C9 plays a role in the metabolism of the following psychotropic drugs: fluoxetine (Prozac), phenytoin (Dilantin), and primidone (Mysoline). Several NSAIDs and Cox-2 inhibitors are substrates of CYP2C9, and patients with reduced CYP2C9 activity may have higher plasma levels of celecoxib (Celebrex), flurbiprofen (Ocufen), piroxicam (Feldene), or meloxicam (Mobic). CYP2C9 plays a minor role in the elimination of diclofenac (Voltaren), sulindac (Clinoril), and naproxen (Aleve).

Cardiovascular medications that are metabolized by CYP2C9 include warfarin (Coumadin), fluvastatin (Lescol), losartan (Cozaar), and irbesartan (Avapro).

The FDA has added a contraindication on the use of siponimod (Mayzent) in patients with a CYP2C9 \*3/\*3 genotype.

Inhibitors or inducers of the CYP2C9 enzyme may modify its activity and change the patient's metabolizer status. This can result in drug-drug interactions when a drug substrate is prescribed with known CYP2C9 inhibitors or inducers.

#### Inhibitors

Some known CYP2C9 inhibitors include: amiodarone (Cordarone), capecitabine (Xeloda), chloramphenicol, cimetidine (Tagamet), co-trimoxazole (Septra), danazol (Danocrine), delavirdine (Rescriptor), disulfiram (Antabuse), efavirenz (Sustiva), etravirine (Intelence), fluconazole (Diflucan), 5-fluorouracil (Adrucil), fluoxetine (Prozac), fluvastatin (Lescol), fluvoxamine (Luvox), gemfibrozil (Lopid), lomitapide (Juxtapid), metronidazole (Flagyl), miconazole (Oravig), oxandrolone (Oxandrin), phenytoin (Dilantin), sulfamethoxazole (Bactrim), sulfinpyrazone (Anturane), tamoxifen (Nolvadex), tigecycline (Tygacil), toremifene (Fareston), voriconazole (Vfend) and zafirlukast (Accolate).

#### Inducers

Some known CYP2C9 inducers include: alpelisib (Piqray), apalutamide (Erleada), aprepitant (Emend), bosentan (Tracleer), carbamazepine (Tegretol), dabrafenib (Tafinlar), elvitegravir (Genvoya, Stribild), enzalutamide (Xtandi), phenobarbital, phenytoin (Dilantin), primidone (Mysoline), rifampin (Rifadin, Rimactane), rifapentine (Priftin), ritonavir (Norvir) and St. John's wort.

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

CYP2D6 enzyme activity defines a normal or abnormal (intermediate, poor, or ultra-rapid) metabolizer status for a given individual. Many alleles have been identified and result in different CYP2D6 isoforms that functionally have normal activity, decreased activity, no activity or in some cases unknown activity. The CYP2D6\*1 (reference or wild-type allele) is inferred when no variants tested by the assay are detected. Genotyping tests usually interrogate for both sequence variants and structural variants and results are used to infer CYP2D6 alleles or haplotypes as defined by PharmVar. Sequence variants include single nucleotide polymorphisms (SNPs) and small insertions and deletions. Structural variations include entire gene deletions (CYP2D6\*5), gene duplication/multiplication (CYP2D6\*1xN, \*2xN and \*4xN), and hybrids with the CYP2D7 gene. Moreover, alleles that contain hybrids can be found on their own (as single entities) or in combination with other gene copies (tandems).

Commonly detected alleles include those with normal function (e.g. CYP2D6 \*1, \*2 and \*35), increased function (e.g. CYP2D6\*1xN, \*2xN), reduced function (e.g. CYP2D6\*9, \*10, \*10-\*36, \*17, \*29, and \*41) and no-function (e.g. CYP2D6 \*3, \*4, \*4N, \*5, \*6, \*7, \*8, \*11, \*12, \*36, \*4xN).

The genotype-phenotype relationship is established using a scoring system that assigns an activity value to every CYP2D6 allele, in order to assign a predicted phenotype. For a given genotype, the activity values of the constituent alleles are added together to calculate the CYP2D6 activity score. This activity score (AS) is then used to assign a predicted phenotype. The AS system was first published in 2008 and was recently refined by an expert group that included both the Clinical Pharmacogenetics Implementation Consortium (CPIC) and the Dutch Pharmacogenetics Working Group (DPWG) members. The group reviewed recent findings and heterogeneities in phenotype assignment.

The consensus method jointly recommended by CPIC and the DPWG redefined the translation of CYP2D6 diplotypes to phenotype as follows:

- CYP2D6 ultra-rapid metabolizers (UMs) when the calculated AS is > 2.25
- CYP2D6 normal metabolizers (NMs) when the calculated AS = x is within the range of  $1.25 \le x \le 2.25$
- CYP2D6 intermediate metabolizers (IMs) when the calculated AS = x is within the range of 0 < x < 1.25
- CYP2D6 poor metabolizers (PMs) when the calculated AS = 0

After literature review, the standardization expert group also obtained consensus to 'downgrade' the activity value for the CYP2D6\*10 allele from 0.5 to 0.25 to better reflect the level of enzyme reduction that is observed with this allele. The group proposed the following activity value when the functional effect of the CYP2D6 allele is known:

- fully functional CYP2D6 alleles are assigned an activity value of 1.0 (e.g. CYP2D6 \*2, \*35).
- reduced function CYP2D6 alleles (except CYP2D6\*10) have an activity value of 0.5 (Note that the value of 0.5 does not indicate a 50%) reduction in activity, but signals decreased function, i.e., has functional activity somewhere between no-function and full function).
- CYP2D6\*10 reduced function allele is assigned an activity value of 0.25.
- non-functional CYP2D6 alleles are assigned an activity value of 0 (e.g. CYP2D6 \*4, \*5, \*36, \*36xN, \*4x2N).

For alleles with two or more gene copies, the value of the allele is multiplied by the number of gene copies (e.g. AS of CYP2D6\*1x3N = 3 calculated as the AS of \*1 which is 1 multiplied by 3). For a tandem, the sum of each allele value is used to assign the score (e.g. AS of CYP2D6\*36-\*10 = 0.25 calculated as the sum of AS of CYP2D6\*36 which is 0 and AS of CYP2D6\*10 which is 0.25).

#### The reference range for CYP2D6 metabolic status is a CYP2D6 \*1/ \*1 genotype, which is consistent with an AS of 2.0 and a normal metabolizer status.

#### **Clinical Implications**

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

There is substantial evidence linking the CYP2D6 polymorphisms to variability in the pharmacological and safety profiles of the following psychotropics: desipramine (Norpramin), imipramine (Tofranil), amitriptyline (Elavil), nortriptyline (Pamelor), haloperidol (Haldol), trimipramine (Surmontil), venlafaxine (Effexor), doxepin (Silenor), aripiprazole (Abilify), atomoxetine (Strattera), risperidone (Risperdal), clomipramine (Anafranil), and pimozide (Orap).

CYP2D6 polymorphisms have been shown to affect the pharmacological and safety profiles of the following analgesics: codeine, tramadol (Ultram), and hydrocodone (Vicodin). Codeine and tramadol are prodrugs that need to be activated by CYP2D6. Poor metabolizers are at high risk of therapy failure when given codeine or tramadol. On the other hand, ultra-rapid metabolizers may experience increased toxicity when given standard dosage of codeine or tramadol. Because CYP3A4 is also involved in the metabolism of oxycodone, patients with abnormal CYP2D6 activity may still experience adequate analgesia when taking this drug. CYP2D6 polymorphism has been shown to affect dihydrocodeine (Synalgos-DC) pharmacokinetics and can potentially alter the response to this drug.

Morphine, oxymorphone (Opana), hydromorphone (Dilaudid), butorphanol (Stadol), fentanyl (Duragesic), buprenorphine (Butrans), methadone (Dolophine), morphine (Avinza), and tapentadol (Nucynta) are not substrates of CYP2D6, and the patient's response to these drugs is not expected to be affected by polymorphisms in this enzyme.

Several important cardiovascular medications are metabolized by CYP2D6, and include: metoprolol (Lopressor), flecainide (Tambocor), and propafenone (Rythmol).

Eliglustat (Cerdelga) is a glucosylceramide synthase inhibitor used for the long-term treatment of adult patients with Gaucher disease type 1. Both the FDA-approved drug label and the EMA Summary of Product Characteristics for this drug state that CYP2D6 ultra-rapid metabolizers may not achieve adequate concentrations of eliglustat to achieve a therapeutic effect. Therefore this drug should not be used in these individuals. Patients who are CYP2D6 intermediate and normal metabolizers have a recommended dose of 84 mg twice daily, while poor metabolizers have a recommended dose of 84 mg once daily.

Cevimeline (Evoxac) is a muscarinic agonist indicated for the treatment of symptoms of dry mouth in patients with Sjögrens Syndrome. Both CYP2D6 and CYP3A are responsible for the metabolism of cevimeline, and this drug should be used with caution in individuals who are CYP2D6 poor metabolizers, as they may be at a higher risk of adverse events.

Inhibitors of the CYP2D6 enzyme may modify its activity and change the patient's metabolizer status. This can result in drug-drug interactions when a drug substrate is prescribed with known CYP2D6 inhibitors. Although there are no known clinical inducers of CYP2D6, the pharmacokinetics of a drug substrate can be affected by inducers of other enzymes (such as CYP3A) that are involved in the metabolism of that drug.

#### Inhibitors

Some known **strong and moderate** CYP2D6 inhibitors include: abiraterone (Zytiga), bupropion (wellbutrin), cinacalcet (Sensipar), cobicistat (Stribild), dacomitinib (Vizimpro), duloxetine (Cymbalta), ecstasy, fluoxetine (Prozac), paroxetine (Paxil), quinidine (Quinidex), rolapitant (Varubi), terbinafine (Lamisil), mirabegron (Myrbetriq), panobinostat (Farydak), peginterferon alfa-2b (Sylatron) and tipranavir/ritonavir (Aptivus).

Some known **weak** CYP2D6 inhibitors include: amiodarone (Cordarone), celecoxib (Celebrex), clobazam (Onfi), desvenlafaxine (Pristiq), diltiazem (Cardiazem), diphenhydramine (Benadryl), Echinacea, escitalopram (Lexapro), febuxostat (Uloric), gefitinib (Iressa), hydralazine (Apresoline), hydroxychloroquine (Plaquenil), imatinib (Gleevec), lorcaserin (Belviq), methadone (Dolophine), perphenazine (Trilafon), propafenone (Rythmol), ranitidine (Zantac), ritonavir (Norvir), sertraline (Zoloft), telithromycin (Ketek), venlafaxine (Effexor) and verapamil (Isoptin, Covera-HS).

## CYP3A4 Monograph

#### **Clinical Utility**

The cytochrome P450 3A4 and 3A5 (CYP3A4 and CYP3A5) account for 40-80% of total CYP in human liver and intestine, respectively. Most importantly, CYP3A enzymes metabolize 50% of commonly used drugs. CYP3A4 and CYP3A5 enzymes have overlapping substrate specificity, and the contribution of CYP3A5 in the overall metabolism is smaller than the one for CYP3A4. The overall CYP3A metabolism status is expected to affect drugs that have a narrow therapeutic index.

#### **Assay Interpretation**

A limited number of variants identified within the CYP3A4 and CYP3A5 genes have been associated with significant alterations in enzyme activity and subsequent variability in therapeutic response. For CYP3A5, individuals with the less prevalent "normal metabolizer phenotype" may metabolize drugs faster than those with the more common "poor metabolizer phenotype". This may result in increased toxicity or loss of efficacy.

The CYP3A4\*1B variant is the most studied, and results in an enzyme with a moderately decreased activity. It occurs in 50% of African-Americans, 3-5% of Caucasians, and <1% of Asians. The CYP3A4\*2, \*3, \*12, and \*17 are also considered decreased activity alleles. Recently, the CYP3A4 \*22 allele has been characterized as a decreased function allele that can be clinically relevant (associated with a decreased clearance of certain substrates). The genotype-phenotype relationship for CYP3A4 is not well established, and individuals are predicted to have a CYP3A4 normal or intermediate metabolic capacity.

#### The reference range for CYP3A4 metabolic status is CYP3A4 \*1/ \*1, which is consistent with a normal metabolizer.

The variant results in an enzyme with no activity, and is the most common variant in the general population. This variant is found on all the CYP3A5\*3 alleles. The CYP3A5 \*6 and \*7 are also no function alleles. The functional effects of the CYP3A5 alleles \*2, \*4, \*5 \*8, and \*9 are not well established. The CYP3A5 \*1 functional allele produces an active enzyme, and is found in 5% of Caucasians, 20% of Asians, and 15-50% of Africans. Individuals with two CYP3A5 no function alleles are classified as poor metabolizers while those carrying one copy of a functional CYP3A5\*1 allele are considered intermediate metabolizers. A subject carrying two copies of the functional CYP3A5\*1 allele is considered a normal metabolizer. CYP3A5 poor metabolizers represent 50% of Asians and 90% of Caucasians.

The reference range for CYP3A5 metabolic status is CYP3A5 \*1/\*1, which is consistent with a normal metabolizer. This genotype is the least prevalent in Caucasians and Asians.

CYP3A4 and CYP3A5 genotypes can help identify patients with high or low overall CYP3A activity. Although these two enzymes metabolize many drugs, the response of only a few (such as narrow therapeutic index drugs) is expected to change significantly by genetic polymorphisms. Fentanyl (Duragesic) is a narrow therapeutic drug that is mainly metabolized by CYP3A. There is limited evidence suggesting that the response to this drug is altered in individuals with abnormal CYP3A activity.

The following drugs used in pain management and various psychiatric conditions are metabolized extensively by CYP3A: fentanyl (Duragesic), oxycodone (Oxycontin), buprenorphine (Suboxone), carbamazepine (Tegretol), quetiapine (Seroquel), ziprasidone (Geodon), alprazolam (Xanax), midazolam (Versed), triazolam (Halcion), nefazodone (Serzone), trazodone (Oleptro), vilazodone (Vibryd), zaleplon (Sonata), and zolpidem (Ambien). CYP3A contributes to a small extent in the elimination of methadone (Dolophine).

Within the major therapeutic classes used in cardiovascular conditions, the following drugs are substantially metabolized by CYP3A: atorvastatin (Lipitor), simvastatin (Zocor), lovastatin (Mevacor), nifedipine (Procardia), verapamil (Verelan), nicardipine (Cardene), felodipine (Plendil), nisoldipine (Sular), clopidogrel (Plavix), prasugrel (Effient), ticagrelor (Brilinta), cilostazol (Pletal), amiodarone (Cordarone), quinidine (Qualaquin), disopyramide (Norpace), losartan (Cozaar), rivaroxaban (Xarelto), and apixaban (Eliquis).

CYP3A metabolism is highly sensitive to inhibition and induction when a patient is taking multiple drugs. In this case, occurrence of drug-drug interactions can have profound effects on the pharmacokinetics, as well as the responses and safety profiles of many CYP3A drug substrates.

#### Inhibitors

Some known **strong** CYP3A inhibitors include: boceprevir (Victrelis), clarithromycin (Biaxin), clofazimine (Lamprene), conivaptan (Vaprisol), grapefruit juice (high dose), idelalisib (Zydelig), itraconazole (Sporanox), ketoconazole (Nizoral), lopinavir, (Kaletra), nefazodone (Serzone), nelfinavir (Viracept), paritaprevir (Technivie), posaconazole (Noxafil), ribociclib (Kisqali), ritonavir (Norvir), saquinavir (Invirase), telaprevir (Incivek), telithromycin (Ketek), tipranavir (aptivus), troleandomycin (TAO) and voriconazole (Vfend).

Some known **moderate** CYP3A inhibitors include: amprenavir (agenerase), aprepitant (Emend), atazanavir (Reyataz), ciprofloxacin (Cipro), darunavir (Prezista), diltiazem (cardizem), erythromycin (Eryc), fosamprenavir (Lexiva), fluconazole (Diflucan), grapefruit juice (low dose), imatinib (Gleevec), quinupristin/dalfopristin (Synercid) and verapamil (Isoptin, Covera-HS).

Some known **weak** CYP3A inhibitors include: amiodarone (Cordarone), amlodipine (Norvasc), atorvastatin (Lipitor), bicalutamide (Casodex), cilostazol (Pletal), cimetidine (Tagamet), fluoxetine (Prozac), fluoxamine (Luvox), ranitidine (Zantac), ranolazine (Ranexa), sertraline (Zoloft) and ticagrelor (Brilinta).

#### Inducers

Some known **strong** CYP3A inducers include: apalutamide (Erleada), carbamazepine (Tegretol), enzalutamide (Xtandi), fosphenytoin (Cerebyx), lumacaftor (Orkambi), phenobarbital, phenytoin (Dilantin), primidone (Mysoline), rifampin (Rifadin), rifapentine (Priftin) and St. John's wort.

Some known **moderate** CYP3A inducers include: artemether (Coartem), bosentan (Tracleer), dabrafenib (Tafinlar), efavirenz (Sustiva), etravirine (Intelence), ivosidenib (tibsovo), modafinil (Provigil), nafcillin (Unipen), nevirapine (Viramune) and rifabutin (Mycobutin).

Some known **weak** CYP3A inducers include: aprepitant (Emend), clobazam (Onfi), dexamethasone (Decadron), Echinacea, fosamprenavir (Lexiva), lesinurad (Zurampic), methylprednisolone (Medrol), midostaurin (Rydapt), oxcarbazepine (Trileptal), pioglitazone (Actos) and rufinamide (Banzel).

## Factor II Monograph

#### **Clinical Utility**

The F2 gene encodes the coagulation factor II, or prothrombin. It is a vitamin K-dependent proenzyme that functions in the blood coagulation cascade. It is a precursor to thrombin, which converts fibrinogen into fibrin, which in turn strengthens a protective clot.

The F2 c.\*97G>A variant (also known as Factor II 20210G>A) in the F2 gene results in increased levels of plasma prothrombin and a concurrent increased risk for thrombosis. Prothrombin-related thrombophilia is characterized by venous thromboembolism (VTE). This risk of thrombosis is also increased when variants exist for other coagulation factors such as F5 c.1601G>A variant (also known as Factor V Leiden), or in presence of non-genetic risk factors such as obesity, injury, surgery, smoking, pregnancy, use of estrogen-containing contraceptives, or replacement therapy. The clinical expression of prothrombin-related thrombophilia is variable, and many individuals may never develop thrombosis, while others may experience venous thrombotic events or pregnancy complications.

#### **Assay Interpretation**

The Factor II thrombophilia is the second most common inherited risk factor for thrombosis. The F2 c.\*97G>A variant (also known as Factor II 20210G>A) is associated with a hypercoagulable state. In the United States, the prevalence of this variant is 1.1% in Caucasians and Hispanics and 0.3% in African-Americans. The prevalence of heterozygosity is 2%-5% in whites and 0%-0.3% in African-Americans. The prevalence of homozygosity is approximately one in 10,000.

#### The reference range for F2 c.\*97G>A variant is F2 c.\*97G>A G/G.

#### **Clinical Implications**

The F2 c.\*97G>A variant is associated with an elevation of plasma prothrombin levels to about 30% above normal in heterozygotes and to 70% above normal in homozygotes. Heterozygotes are at a 2- to 5-fold increased risk of an initial VTE. The risk for VTE in F2 c.\*97G>A homozygotes is not well defined but is presumed to be higher than in F2 c.\*97G>A heterozygotes. F2 c.\*97G>A homozygotes tend to develop thrombosis more frequently and at a younger age. Individuals who are doubly heterozygotes for F5 c.1601G>A variant and F2 c.\*97G>A variant have an estimated 20-fold increased risk when compared to individuals without either variant suggesting a multiplicative elevation in risk. Certain circumstantial factors can increase the risk of thrombosis, and include: travel, central venous catheter use, pregnancy, oral contraceptive use, hormone replacement therapy (HRT), selective estrogen receptor modulators (SERMs), organ transplantation, injury, age, and surgery.

### Factor V Leiden Monograph

#### **Clinical Utility**

The F5 gene encodes the coagulation factor V. In normal conditions, Factor V is inactivated during the clotting process by the activated protein C (APC). In subjects with Factor V Leiden thrombophilia, a variant in the gene produces a Factor V that cannot be inactivated normally by APC. As a result, the clotting process remains active longer than usual, leading to more thrombin generation. This hypercoagulable state is also increased when other variants exist in other coagulation factors such as F2 c.\*97G>A variant (also known as Factor II 20210G>A), or in the presence of non-genetic risk factors such as obesity, injury, surgery, smoking, pregnancy, or use of estrogen-containing contraceptive or estrogen containing replacement therapy. The clinical expression of Factor V Leiden thrombophilia is variable. Many individuals may never develop thrombosis, while others may experience venous thrombotic events or pregnancy complications. Certain circumstantial factors can increase the risk of thrombosis, and include: travel, central venous catheter use, pregnancy, oral contraceptive use, hormone replacement therapy (HRT), selective estrogen receptor modulators (SERMs), organ transplantation, injury, age, and surgery. These factors are associated with the first thrombotic episode in at least 50% of individuals with a F5 c.1601G>A variant.

#### **Assay Interpretation**

The F5 c.1601G>A variant (also known as Factor V Leiden) is the most common known inherited risk factor for thrombosis. The F5 c.1601G>A variant refers to a base change (from G to A at position 1691) in the gene. As a result, Factor V is inactivated to a lesser extent and persists for longer in the circulation, leading to hypercoagulability. In the US, the frequency of the F5 c.1601G>A variant varies by ethnicity, with about 5% of Caucasians, 2% of Hispanics, and 1% of African-Americans having one variant. Only 1 in 5000 individuals have two F5 c.1601G>A variants.

#### The reference range for F5 c.1601G>A variant is F5 c.1601G>A G/G.

#### **Clinical Implications**

About 1 in 1000 people in the U.S. experience a first venous thromboembolism (VTE) each year. VTE is caused by inherited and environmental factors, and while the F5 c.1601G>A variant is present in only 15-20% of individuals with a first VTE, it is found in 50% of individuals with recurrent VTE or estrogen-related thrombosis. The risk for VTE is increased 3- to 8-fold in F5 c.1601G>A heterozygotes and 9- to 80-fold in homozygotes. This risk is increased further if other genetic or circumstantial factors are present. A heterozygote individual for both the F5 c.1601G>A variant and the F2 c.\*97G>A variant (compound heterozygote) has an even greater risk of VTE (20-fold) than an individual with a variant in only one factor. This illustrates the multiplicative effect of these two factors on overall thrombotic risk.

## MTHFR Monograph

#### **Clinical Utility**

Methylenetetrahydrofolate reductase (MTHFR) is involved in folate metabolism and is essential for the remethylation of homocysteine. Two common variants in the MTHFR gene: c.665C>T (legacy name 677C>T) and c.1286A>C (legacy name 1298A>C), result in an enzyme with decreased activity, which is linked to increased plasma homocysteine levels (i.e. hyperhomocysteinemia). Mild to moderate hyperhomocysteinemia has been identified as a risk factor for venous thromboembolism and other cardiovascular diseases such as coronary heart disease and stroke. Other conditions in which hyperhomocysteinemia is found, include recurrent pregnancy loss, placental infarction and birth defects. However, the causal role of MTHFR variants in these conditions is not well established.

#### **Assay Interpretation**

The approximate minor allele frequencies for most populations are 30-50% for the MTHFR c.1286A>C variant and 18-30% for the MTHFR c.665C>T variant. Heterozygotes and homozygotes for the MTHFR c.665C>T variant have 60% and 30% of normal MTHFR activity, respectively. Heterozygotes and homozygotes for the MTHFR c.1286A>C variant have 80% and 60% of normal MTHFR activity, respectively.

## The reference ranges for both variants of MTHFR are c.665C>T C/C and c.1286A>C A/A. This is consistent with a normal MTHFR activity.

#### **Clinical Implications**

The MTHFR assay provides information about potential causes of elevated homocysteine, and approaches for addressing it.

- Homozygosity for the MTHFR c.665C>T variant (individual with MTHFR c.665C>T T/T genotype) predisposes for hyperhomocysteinemia (especially during times of folate insufficiency) and an increase in premature cardiovascular disease. Measurement of total plasma homocysteine is informative in this case.
- Compound heterozygosity (individual with MTHFR c.665C>T C/T and MTHFR c.1286A>C A/C genotypes) is not associated with an increase in plasma homocysteine level. Measurement of total plasma homocysteine is informative in this case.
- Heterozygosity or homozygosity for the MTHFR c.1286A>C A>C variant alone (individual with MTHFR c.1286A>C A/C or MTHFR c.1286A>C C/C genotypes) does not increase homocysteine levels. Similarly, heterozygosity for the MTHFR c.665C>T variant alone (individuals with MTHFR c.665C>T C/T genotype) does not increase homocysteine levels.
- Hyperhomocysteinemia related to MTHFR genetic variants has been associated with neural tube defects, stillbirths and recurrent pregnancy loss. However, because hyperhomocysteinemia is multifactorial, involving a combination of other genetic, physiologic and environmental factors, the presence of MTHFR variants in an individual should not be used alone to predict the risk of these conditions.
- MTHFR in depression: Low MTHFR activity may exacerbate folate deficiency in patients with depression and may increase the risk of depressive relapse or delay the response to antidepressants. Testing for homocysteine levels and serum folate levels are recommended in patients with depression. Methylfolate may substantially benefit patients with hyperhomocysteinemia and depression when used as an adjuvant to antidepressant medication.
- The response to methotrexate, a drug used in cancer and autoimmune diseases, is affected by the presence of MTHFR genetic variants. Methotrexate intolerance is observed in individuals that are heterozygous or homozygous for the MTHFR c.665C>T variant.

## **OPRM1** Monograph

#### **Clinical Utility**

"Mu" opioid receptors are the most important site of action of opioid drugs. Single polymorphisms in the human mu-opioid receptor (OPRM1) have been investigated for their role in human nociception, opiate efficacy, and addiction.

#### **Assay Interpretation**

The variant mostly studied is a single substitution at position 118, from an adenine to a quanine (A118G). This variant reduces the OPRM1 receptor signaling efficiency induced by exogenous opioids. Reduced OPRM1 mRNA expression levels were observed in carriers of the G variant. The variant allele (G) is present in 7-15% of Caucasians, 1.5% of African-Americans, and up to 48.5% of Asians. The major interest of this particular SNP is due to its pharmacological and physiological consequences; however the exact mechanism by which the altered receptor influences opioid analgesia is still unresolved. The presence of the G allele seems to reduce the effect of exogenous agonists but increase the effects of exogenous antagonists.

#### The reference range for the A118G SNP is A118G AA, and is associated with a normal OPRM1 receptor signaling efficiency.

#### **Clinical Implications**

The presence of the G allele (A118G) seems to be associated with pain sensitivity as well as opioid dosage requirements. But only weak evidence of these associations is available to date. It is suggested that patients carrying the G allele report higher intensity pain. In terms of drug response, patients with the G allele have a favorable response to the anti-addictive drug naltrexone. Several studies conducted in postsurgical settings or in cancer analgesia showed that G allele carriers require slightly higher doses of morphine or fentanyl. This association still needs to be confirmed in larger studies and does not hold in other situations such as labor pain.

## SLCO1B1 Monograph

#### **Clinical Utility**

The SLCO1B1 gene encodes a liver-specific transporter involved in the removal of endogenous compounds (bile acids, bilirubin) and drugs such as statins from the blood to the liver. Some variants of the SLCO1B1 gene result in a low-functioning protein, which impairs statin clearance, and may lead to an increased risk of muscle pain, tenderness, or weakness, called myopathy. Certain medications can potently inhibit SLCO1B1, causing clinically significant drug interactions.

#### **Assay Interpretation**

 NAME:
 Patient io284w9

 ACC #:
 io284w9

 Image: Content of the second secon

SPECIMEN DETAILS

SPECIMEN TYPE: COLLECTION DATE: RECEIVED DATE: REPORT DATE: 11/11/2022

FOR ACADEMIC PURPOSES ONLY - NOT FOR CLINICAL USE

The functional SLCO1B1 activity (phenotype) is estimated from the genotype at 521T>C. Non-carriers of the 521T>C variant are predicted to have a SLCO1B1 normal function, those with one copy of the 521T>C variant have a SLCO1B1 decreased function, and those with two copies of the variant have poor SLCO1B1 function.

There are several variants of the SLCO1B1 that define over 15 alleles. One relatively common variant 521T>C (rs4149056) results in SLCO1B1 decreased function, which affects the transport of drug substrates such as statins. This variant is present alone on the \*5 allele and in presence with another variant (388A>G; rs2306283) on the \*15 allele. Both alleles are low-activity alleles (reduced hepatic uptake), and have a combined frequency of 15-20% in Caucasians, 10-15% in Asians, and 2% in sub-Saharan Africans and African-Americans.

#### The reference range for the 521T>C mutation of SLCO1B1 is 521 TT. This is consistent with normal SLCO1B1 function.

#### **Clinical Implications**

All statins are substrates of SLCO1B1, but the effects of SLCO1B1 genetic polymorphism differ between individual statins. The effect is the largest on simvastatin, and individuals with the 521T>C variant have increased levels of the active simvastatin form. The variant is strongly associated with simvastatin-induced myopathy (with or without CK elevation), especially with high-dose simvastatin therapy. More than 60% of the myopathy cases could be attributed to its presence. The clinical spectrum of statin-induced myopathy ranges from a mild and common myalgia to a life-threatening and rare rhabdomyolysis. Other known risk factors for statin-induced myopathy include a high-statin dose, interacting drugs that raise statin levels, age, hypothyroidism, and certain inherited muscle disorders.

At therapeutic doses, the apparent sensitivity levels of the five statins to the presence of the 521T>C variant are

simvastatin>pitavastatin>atorvastatin>pravastatin>rosuvastatin. Carriers of the 521 T>C variant should avoid high-dose simvastatin therapy. These patients can take other statins, such as atorvastatin, pitavastatin, rosuvastatin, or pravastatin, but at reduced doses. Fluvastatin is not affected by the 521 T>C variant and could therefore be considered a suitable alternative.

Other drugs that are substrates of SLCO1B1 transporter include enalapril, olmesartan, valsartan, atrasentan, repaglinide, nateglinide, methotrexate, and bosentan. However, there is insufficient evidence documenting the impact of the 521 T>C variant on the systemic exposure and safety profile of these drugs.

#### Inhibitors

Inhibitors of SLCO1B1 transporter may alter its activity and result in increased levels of drug substrates. These include boceprevir (Victrelis), clarithromycin (Biaxin), cyclosporine (Gengraf, Neoral, Restasis, Sandimmune), eltrombopag (Promacta), gemfibrozil (Lopid), paritaprevir (Technivie), protease inhibitors, simeprevir (Olysio), telaprevir (Incivek) and teriflunomide (Aubagio).

#### Inducers

Inducers of SLCO1B1 transporter include: apalutamide (Erleada).

### VKORC1 Monograph

#### **Clinical Utility**

The Vitamin K epoxide reductase complex, subunit 1 (VKORC1) is the target of anticoagulants such as warfarin, acenocoumarol and phenprocoumon. VKORC1 catalyzes the conversion of oxidized Vitamin K to reduced Vitamin K. By inhibiting this conversion, warfarin leads to decreased availability of the reduced Vitamin K that serves as a cofactor for gamma-glutamyl carboxylase and blocks the formation of functionally-active clotting factors, resulting in reduced coagulation. Polymorphisms within the VKORC1 gene result in variable expression levels of the VKORC1 enzyme and altered response towards coumarin anticoagulants. VKORC1 genetic testing defines three clinical phenotypes: high, moderate, and low sensitivity to warfarin. VKORC1 genetic testing is usually used in conjunction with CYP2C9 and CYP4F2 genetic testing to optimize warfarin dosing and minimize the risks of bleeding or thrombotic complications.

#### **Assay Interpretation**

Several relevant variants in the VKORC1 gene have been identified and correlate well with warfarin dose requirements. In Europeans, the genotype for a single variant (-1694G>A; rs9923231) accounts for 25% of variability in warfarin dose requirements, with the minor A allele associated with lower doses. This association is also observed in East Asians, where the minor allele occurs more frequently than in Europeans (88% vs 41%). In Africans, the minor allele frequency for VKORC1 -1639G>A is 10% which is considerably lower than in Europeans. Several studies in Africans and African-Americans identified common variants that are associated with higher warfarin dose requirements in patients of African descent.

#### The reference range for VKORC1 -1639G>A is G/G and is associated with a normal VKORC1 enzyme expression phenotype.

#### **Clinical Implications**

The common VKORC1 -1639G>A variant is associated with low-dose warfarin requirements. When CYP2C9 and VKORC1 genotypes are combined with other patient-specific parameters such as demographic (age, weight, height), clinical (disease, co-medications), and environmental factors (smoking), they account for 50% of warfarin dose variation between individuals. Several validated warfarin pharmacogenetic dosing algorithms have been developed and are available to calculate initial and maintenance warfarin doses in both adults and children. Moreover, the FDA prescribing label for warfarin includes genotype-specific dose ranges based on CYP2C9 and VKORC1 genotypes.
